

## **DECLARATION**

I, Junji KAMATA, Patent Attorney, of SIKs & Co., 8th Floor, Kyobashi-Nisshoku Building 8-7, Kyobashi 1-Chome, Chuo-ku, Tokyo 104-0031 JAPAN, hereby declare that I am the translator of the certified official copy of the documents in respect of an application for a patent filed in Japan on August 3, 2000 under Patent Application No. 236044/2000 and that the following is a true and correct translation to the best of my knowledge and belief.

Dated: June 13, 2005

Junji KAMATA

PATENT OFFICE

JAPANESE GOVERNMENT

This is to certify that the annexed is a true copy of the following application as filed with this office.

Date of Application : August 3, 2000  
Application Number : Patent Application No. 2000-236044  
Applicant(s) : FUJI PHOTO FILM CO., LTD.

April 6, 2001

Kozo OIKAWA

Commissioner, Patent Office

**【Document name】** Specification

**【Title of the invention】** Method for preparing grains of silver salt of organic acid and thermally processed image recording material

**【Claims】**

**【Claim 1】** A method for preparing an aqueous dispersion of grains of silver salt of an organic acid that is obtained by dispersing the silver salt grains of the organic acid into an aqueous solvent; which comprises the steps of reacting (1) a solution containing silver ion in water or in a mixture of organic solvent and water with (2) a solution or suspension containing an alkali metal salt of the organic acid in water or in a mixture of an organic solvent and water, or in an organic solvent, to obtain a silver salt of the organic acid, and conducting dispersion with a high pressure homogenizer or high speed rotary homomixer in the presence of a dispersing agent, and removing by-product salts by ultrafiltration.

**【Claim 2】** A method for preparing an aqueous dispersion of grains of silver salt of an organic acid that is obtained by dispersing the grains of silver salt of the organic acid into an aqueous solvent; which comprises the steps of reacting (1) a solution containing silver ion in water or in a mixture of organic solvent and water with (2) a solution or suspension containing an alkali metal salt of the organic acid in water or in a mixture of an organic solvent and water, or in an organic solvent, to obtain a silver salt of the organic acid, and conducting dispersion with a high pressure homogenizer or high speed rotary homomixer in the presence of a dispersing agent with by-product salts being removed by ultrafiltration.

**【Claim 3】** The method for preparing an aqueous dispersion of grains of silver salt of an organic acid according to Claim 1 or 2, wherein the dispersion agent has a molecular weight of 3000 or less and is an anionic surfactant having 8–40 carbon atoms.

**【Claim 4】** The method for preparing an aqueous dispersion of grains of silver salt of an organic acid according to any one of Claims 1–3, wherein the dispersing agent is used at a concentration of 1–30 weight % of dispersolid.

**【Claim 5】** The method for preparing an aqueous dispersion of grains of silver salt of an organic acid according to any one of Claims 1–4, wherein concentration of the grains of silver salt of the organic acid is 1–10 weight % immediately after the reaction.

**【Claim 6】** The method for preparing an aqueous dispersion of grains of silver salt of an organic acid according to any one of Claims 1–5, wherein, after the by-product salts are removed by the ultrafiltration, concentration operation is performed by the ultrafiltration.

**【Claim 7】** The method for preparing an aqueous dispersion of grains of silver salt of an organic acid according to any one of Claims 1–5, wherein, after electric conductivity reached within the range of from 20  $\mu\text{S}/\text{cm}$  to less than 300  $\mu\text{S}/\text{cm}$  as a result of the removal of the by-product salts by the ultrafiltration, the dispersion is concentrated to a concentration of 10–70 weight % by the ultrafiltration.

**【Claim 8】** A method for producing a thermally processed image recording material comprising a silver salt of an organic acid, a reducing agent for silver ions and a binder on at least one surface of a support, which comprises a step of applying a coating solution for image-forming layer containing an aqueous dispersion of grains of silver salt of an organic acid prepared by the method according to any one of Claims 1–7.

**【Claim 9】** A method for producing a thermally processed image recording material comprising a silver salt of an organic acid, a reducing agent for silver ions and a binder on at least one surface of a support, which comprises a step of applying a coating solution for image-forming layer containing an aqueous dispersion of grains of silver salt of an organic acid prepared by the preparation method

according to Claim 8

**[Claim 10]** A thermally processed image recording material which is prepared by the method according to claim 8 or claim 9.

**[Detailed description of the invention]**

**[0001]**

**[Filed of the invention]**

The present invention relates to a method for preparing an aqueous dispersion of grains of silver salt of an organic acid which can be used in a thermally processed image recording materials, especially photothermographic material. The present invention also relates to a thermally processed image recording material that utilizes the aqueous dispersion of grains of silver salt of the organic acid, and a method for producing the material.

**[0002]**

**[Relevant art]**

In recent years, reduction of amount of waste processing solutions is strongly desired in the field of medical diagnosis from the standpoints of environmental protection and space savings. Therefore, techniques relating to photothermographic materials for use in photographic-art processes and medical diagnosis are required which enables efficient exposure by a laser image setter or laser imager and formation of a clear black image having high resolution and sharpness. Such photothermographic materials can provide users with a simple and non-polluting heat development processing system that eliminates the use of solution-type processing chemicals.

**[0003]**

Methods for forming an image by heat development are described in, for example, U.S. Patent Nos. 3,152,904 and 3,457,075 and D. Klosterboer, "Thermally Processed Silver Systems", Imaging Processes and Materials, Neblette, 8th ed., compiled by J. Sturge, V. Walworth and A. Shepp, Chapter 9, p.279, (1989).

**[0004]**

Such a photothermographic material contains a reducible non-photosensitive silver salt (e.g., organic acid silver salt), a photocatalyst (e.g., silver halide) in a catalytically active amount and a reducing agent for silver, which are usually dispersed in an organic binder matrix. The photothermographic material is stable at normal temperature, and when the material is heated at a high temperature (e.g., 80°C or higher) after light exposure, black silver images are produced through an oxidation-reduction reaction between the silver halide or reducible silver salt (which functions as an oxidizing agent) and the reducing agent. The oxidation-reduction reaction is accelerated by catalytic action of a latent image of the silver halide generated upon exposure. The silver produced by the reaction of the reducible silver salt in exposed areas provides a black image in contrast to non-exposed areas whereby image can be formed.

**[0005]**

The silver source used in these systems is generally a silver salt of an organic acid, and various methods for producing it have been known. For example, there can be mentioned the method of preparing a silver salt of an organic acid under coexistence of water and a hardly water-soluble solvent as disclosed in Japanese Patent Laid-open Publication (Kokai, hereinafter referred to as JP-A) 49-93310, JP-A-49-94619 and JP-A-53-68702, the method of preparing a silver salt of an organic acid in an aqueous solution as disclosed in JP-A-53-31611, JP-A-54-4117 and JP-A-54-46709, the method of preparing a silver salt of an organic acid in an organic solvent as disclosed in JP-A-57-186745, JP-A-47-9432 and U.S. Patent No. 3,700,458 and so forth. Basically, the preparation is carried out by heating an organic acid to a

temperature higher than its melting point to melt it in water, adding sodium hydroxide or an alkali metal salt, with vigorous stirring, and then adding a solution containing silver ions in order to convert the alkali soap into silver soap.

**[0006]**

Such alkali soap forms micelles in an aqueous solution, and gives a solution of whitely turbid appearance. The reaction from such a micelle state to the silver soap often suffers from problems concerning production stability. Therefore, as a method for obtaining the alkali soap as a uniform solution, a method of using a mixed solution of water and alcohol as the solvent is disclosed in JP-A-55-40607.

**[0007]**

Further, as shown in name, alkali soap presents alkalinity. Accordingly, the silver soap will be prepared under a high pH condition in the above case. However, addition of a solution containing silver ions into an alkaline solution produces silver oxide as a by-product. Further, it also generates unintended silver nuclei produced by a trace amount of reducing contaminants, which are unavoidable in view of production process and exhibit high reducing property due to the high pH. Such by-products are extremely disadvantageous from the viewpoint that they degrade performance of photothermographic materials, in particular, they cause undesired fog. In this respect, the aforementioned problems are not solved even in the method disclosed in JP-A-55-40607, which aims at obtaining a uniform solution in order to suppress the generation of the by-products.

**[0008]**

Further, JP-A-9-127643 discloses a method for producing a silver salt by simultaneous addition of measured amounts of an alkali metal salt solution and a silver nitrate solution, and refers to simultaneous addition of a solution of sodium behenate in a mixture of water and isopropyl alcohol and a solution of silver nitrate. This method can at least shift the pH of the reaction from the high pH region to a neutral region, and thus it is a preferred method for reducing the generation amount of silver oxide. However, isopropyl alcohol shows weak reducing property, and this makes the method insufficient as a method for completely solving the problem of fog.

Thus, silver salt of a fatty acid should be carefully prepared. In preparing the silver salt of an organic acid, it is required to eliminate reducible materials as possible and control a grain size and grain shape. However, the conventional methods fail to satisfy these requirements.

**[0009]**

Many conventional thermally processed image recording materials utilizing silver salt of a fatty acid is prepared by coating a coating solution containing an organic solvent such as toluene, methyl ethyl ketone and methanol, to form a photosensitive layer. Use of an organic solvent as a solvent is unfavorable due to insufficient safety in the production process, bad influence to human bodies, high cost for solvent recovery and others. Additionally, use of an organic solvent is not proper in producing a thermally processed image recording material which aims at preservation of environment.

**[0010]**

When a water-soluble binder is used, an image-forming layer can be formed by a coating solution containing water as a solvent. This is advantages in environment and cost. However, the binders of the water-soluble polymers have poor compatibility with a silver salt of fatty acid. There provides the problems that a practical coated surface can not be obtained, color tone of silver image formed in developed area is brownish or yellowish which is far from a preferable black color, the fog level is high. Thus, the prepared materials have poor commercial value.

**【0011】**

In order to obtain a uniform dispersion practically usable as a coating solution containing a silver salt of a fatty acid, it is necessary to obtain a state that the silver salt of a fatty acid is finely dispersed in a solvent without aggregation. For this reason, it is necessary to develop a method for dispersing the silver salt of a fatty acid as fine grains. Usually used is a method comprising separating the formed hydrophobic grains of silver salt of a fatty acid as solid by filtration, mixing a dispersing agent with the solid, and dispersing the mixture again, as described in Imaging Processes and Materials, supra.

**【0012】**

As the method for dispersing a silver salt of a fatty acid as fine grains, the method of mechanically dispersing it in the presence of a dispersing aid by means of known pulverization mean. However, this method not only produces only a coating solution containing a lot of aggregated particles, and a coating solution that gives bad coated surface quality. Because the method highly possibly grinds primary grains of a silver salt of a fatty salt originally crystallized as a hardly wafer-soluble salt without any selectivity, silver nuclei are formed at crystal cleavage surfaces and causes increase of fog.

**【0013】**

Then, several methods have been proposed, wherein the primary grains obtained during the reaction of a solution of alkali metal salt and a solution containing silver ions are utilized as they are, not separating the silver salt of a fatty acid as solid and finely dispersing it. For example, JP-A-8-234358 discloses a method of adding silver nitrate to an aqueous dispersion in which fine grains of an alkali salt of a fatty acid are dispersed, and desalting the obtained dispersion of a silver salt of a fatty acid by ultrafiltration. The above reference further refers to enhancement of the dispersion stability by carrying out the ultrafiltration for a dispersion preliminarily containing water-soluble protective colloids such as polyvinyl alcohol and gelatin. However, the shape of the silver salt of a fatty acid obtained by this method is limited to an acicular shape, and in addition, it is difficult to control the grain size in this method. Therefore, it is still insufficient for stably obtaining performance of low fog, high blackening concentration and low haze, which are desired for photothermographic materials.

**【0014】**

Further, JP-A-9-127643 discloses a method of directly desalting a dispersion of a silver salt of a fatty acid obtained by simultaneous addition of measured amounts of a solution of an alkali metal salt and a silver nitrate solution by means of dialysis or ultrafiltration. By this method, at least the primary grains obtained during the crystallization of the silver salt of a fatty acid can be introduced into a photosensitive layer as they are without degrading the grains. However, problems concerning aggregation of grains under a high salt concentration circumstance, increase of viscosity upon concentration of the dispersion and so forth are not solved, and thus this method is still insufficient as practical means for obtaining a uniform dispersion.

**【0015】**

**【Problems to be resolved by the invention】**

In consideration of the problems of the prior arts, the object of the present invention is to provide a method of preparing a stable dispersion, that can provide a coated surface of high quality, without isolating a silver salt of an organic acid as a solid and distributing it again. In particular, the object of the present invention is to provide a method in which increase in viscosity in a concentration process by ultrafiltration and decrease in speed at ultrafiltration are

suppressed. Further, the object of the prevent intention is to provide a thermally processed image recording material exhibiting low fog, high black concentration and low haze, and a method for preparing the material.

**[0016]**

The inventors conducted extensive study and found that efficient concentration can be conducted with suppressing increase in viscosity in a concentration process by ultrafiltration, decrease in speed at ultrafiltration and blocking of pipeline when dispersion is carried out before or during the concentration process by ultrafiltration, whereby the present invention was provided.

The present invention provides a method for preparing an aqueous dispersion of grains of silver salt of an organic acid that is obtained by dispersing the silver salt grains of the organic acid into an aqueous solvent; which comprises the steps of reacting (1) a solution containing silver ion in water or in a mixture of organic solvent and water with (2) a solution containing an alkali metal salt of the organic acid in water or in a mixture of an organic solvent and water, or in an organic solvent, to obtain a silver salt of the organic acid, and conducting dispersion with a high pressure homogenizer or high speed rotary homomixer in the presence of a dispersing agent, and removing by-product salts by ultrafiltration. The present invention also provides a method for preparing an aqueous dispersion of grains of silver salt of an organic acid that is obtained by dispersing the grains of silver salt of the organic acid into an aqueous solvent; which comprises the steps of reacting (1) a solution containing silver ion in water or in a mixture of organic solvent and water with (2) a solution containing an alkali metal salt of the organic acid in water or in a mixture of an organic solvent and water, or in an organic solvent, to obtain a silver salt of the organic acid, and conducting dispersion with a high pressure homogenizer or high speed rotary homomixer in the presence of a dispersing agent with by-product salts being removed by ultrafiltration.

**[0017]**

A dispersing agent using in the present invention is preferably having a molecular weight of 3000 or less and anionic surfactant of 8-40 carbon atoms. The concentration of the dispersion is preferably 1-30 weight %, more preferably 3-20 weight % of the dispersolid. The concentration of the grains of silver salt of an organic acid is preferably 1-10 weight % immediately after the above reaction and preferably concentrated by ultrafiltration after the by-product salts are removed by ultrafiltration. After the electric conductivity comes to be 20  $\mu\text{S}/\text{cm}$  or more to less than 300  $\mu\text{S}/\text{cm}$  due to the removal of by-product salts by the ultrafiltration, the dispersion can be preferably concentrated to a concentration of 10-70 weight %, more preferably 20-50 weight %.

**[0018]**

The present invention further provides a method for producing a thermally processed image recording material comprising a silver salt of an organic acid, a reducing agent for silver ions and a binder on at least one surface of a support, which comprises a step of applying a coating solution for image-forming layer containing an aqueous dispersion of grains of silver salt of an organic acid prepared by any one of the aforementioned preparation methods. The coating solution for image-forming layer preferably contains a photosensitive silver halide and a polymer showing an equilibrated moisture content of 2 weight % or less at 25°C and relative humidity of 60% in the form of latex as the binder, and 30 weight % or more of the solvent of the coating solution preferably consists of water.

It should now be noted that, in this specification, any notation using a word "to" indicates a range defined by values placed before and after such word, where both ends of such range are included as minimum and maximum values.

**【0019】**

**【Detailed description of the preferred embodiment】**

Hereafter, it describes a method for preparing an aqueous dispersion of grains of silver salt of an organic acid, a thermally processed image recording material and its method of preparation according to the present invention. In a method of preparing an aqueous dispersion of grains of silver salt of an organic acid, the silver salt of organic acid is prepared by reacting (1) a solution containing silver ion in water or in a mixture of organic solvent and water (hereinafter, it shows "a solution of silver ion") with (2) a solution or suspension containing an alkali metal salt of the organic acid in water or in a mixture of an organic solvent and water, or in an organic solvent (hereinafter, it shows "an alkali metal salt of organic acid").

**【0020】**

As the ion source for a solution containing silver ion used in the present invention, water-soluble silver salt can be used. As the water-soluble silver salt, silver nitrate is preferably used. The concentration of the silver salt in the solution containing silver ions is preferably 0.03–6.5 mol/L, more preferably 0.1–5 mol/L. The pH of the solution containing silver ions is preferably 1–6, more preferably 1.5–4. For the pH adjustment, acids and alkaline usually used for pH adjustment may be added to the solution containing silver ions. As the solvent of the solution containing silver ions used for the present invention, either water or a mixture of water and an organic solvent is used. The organic solvent used for the solution containing silver ions is not particularly limited so long as it is miscible with water. However, those degrading photographic performance are not preferred. While preferred solvents are water-miscible alcohols and acetone, a tertiary alcohol having 4–6 carbon atoms is preferably used. When a tertiary alcohol having 4–6 carbon atoms is used, the tertiary alcohol constitute 70 volume % or less, preferably 50 volume % or less, of the total volume of the solution containing silver ions. Temperature of the solution containing silver ions is preferably 1–60°C, more preferably 5–40°C. When a solution containing silver ions and an aqueous tertiary alcohol solution of organic acid alkali metal salt are simultaneously added as described below, the temperature is most preferably 5–15°C.

**【0021】**

The organic acid moiety for the alkali metal salt of an organic acid is selected from those stable to light at an ambient temperature as a silver salt, but when its silver salt is heated at 80°C or higher in the presence of a light exposed photocatalyst (e.g., latent images of photosensitive silver halide) and a reducing agent, it produces a silver image. The organic acid is preferably a long chain aliphatic carboxylic acid containing 10–30 carbon atoms, more preferably 12–26 carbon atoms. Preferred examples of the aliphatic carboxylic acid include cerotic acid, lignoceric acid, behenic acid, erucic acid, arachidic acid, stearic acid, oleic acid, lauric acid, caproic acid, myristic acid, palmitic acid, maleic acid, fumaric acid, tartaric acid, linolic acid, butyric acid, camphoric acid and mixtures thereof. More preferred are behenic acid, arachidic acid, stearic acid, oleic acid, lauric acid, caproic acid, myristic acid, palmitic acid, and mixtures thereof.

As the alkali metal moiety for the alkali metal salt of an organic acid, sodium, potassium and so forth can be mentioned. An alkali metal salt of an organic acid can be prepared by adding sodium hydroxide, potassium hydroxide or the like to an organic acid. In this treatment, it is preferable to use the alkali in an amount less than the equivalent of the organic acid to remain unreacted organic acid. In this case, the amount of the remaining organic acid is preferably 3–5 mole %, more preferably 3–30 mole %, with respect to the total organic acid. Further, it may be prepared by adding an alkali in an amount exceeding the desired amount, and then adding an acid such as nitric acid and sulfuric acid to neutralize excessive alkali substance.

**[0022]**

The concentration of the alkali metal salt of an organic acid in the solution containing an alkali metal salt of an organic acid used for the present invention is preferably 5–50 weight %, more preferably 7–45 weight %, further preferably 10–40 weight %. The solvent used for the solution containing an alkali metal salt of an organic acid used for the present invention may be any one of water, an organic solvent and a mixture of water and an organic solvent. When a mixture of water and an organic solvent is used, the amount of the organic solvent is preferably 3–70 volume %, more preferably 5–50 volume %, with respect to the volume of water. In this case, since the optimum solvent volume varies depending on the reaction temperature, the optimum amount is desirably determined trial-and-error basis. In the present invention, a mixed solvent of water and a tertiary alcohol having preferably not more than 15 carbon atoms, more preferably not more than 10 carbon atoms, particularly preferably 4 to 6 carbon atoms, is preferably used as the solvent of the solution containing an alkali metal salt of an organic acid for ensuring uniformity of the solution. Tertiary alcohols in which the number of carbon atoms exceeds 6 may not be preferred since their miscibility with water becomes poor. Among the tertiary alcohols having 4 to 6 carbon atoms, most preferred is tert-butanol as its miscibility with water is the highest of all. Alcohols other than such tertiary alcohols may also be unfavorable since they have a reducing property and adversely affect the process of forming the silver salt of an organic acid. The amount of the tertiary alcohols is preferably 3–70 volume %, more preferably 5–50 volume %, with respect to the volume of water. Temperature of the solution containing an alkali metal salt of an organic acid, which is added for the reaction, is preferably maintained at a temperature required for avoiding crystallization or solidification of the alkali metal salt of an organic acid. Specifically, it is preferably 50–90°C, more preferably 60–85°C, most preferably 65–85°C. Further, the temperature is preferably controlled to be a constant temperature within the aforementioned range in order to control the reaction temperature to be constant. For the pH adjustment, acids and alkalines usually used for pH adjustment may be added to the solution containing an alkali metal salt of an organic acid.

**[0023]**

The solution containing silver ions and the solution containing an alkali metal salt of an organic acid used for the present invention may be added with compounds of the formula (1) described in JP-A-62-65035, water-soluble group-containing N-heterocyclic compounds such as those described in JP-A-62-150240, inorganic peroxides such as those described in JP-A-50-101019, sulfur compounds such as those described in JP-A-51-78319, disulfide compounds such as those described in JP-A-57-643, hydrogen peroxide and so forth.

**[0024]**

In the present invention, the silver salt of an organic acid is prepared by reacting a solution containing silver ions and a solution containing an alkali metal salt of an organic acid in mixing means. Since sealed mixing means is preferably used as the mixing means, the present invention will be explained by referring to a case utilizing sealed mixing means.

**[0025]**

A preferred method is a method in which the process contains a period where the solution containing silver ions and the solution containing an alkali metal salt of an organic acid are simultaneously added to sealed mixing means (simultaneous addition method). According to the simultaneous addition method, mean grain size of the silver salt of an organic acid can be controlled to achieve narrow grain size distribution. In the simultaneous addition method, it is desirable that 10–100 volume %, more preferably 30–100 volume %, particularly preferably 50–100

volume %, of the total volume to be added is simultaneously added. It is preferable to simultaneously add the solution containing silver ions and the solution containing an alkali metal salt of an organic acid in substantially equimolar amounts. In a case where either one is added in advance, it is desirable that the solution containing silver ions is added first. The amount added in advance is preferably from 0-50 volume %, more preferably from 0-25 volume %, of the total amount to be added. Furthermore, a method described in JP-A-9-127643 wherein pH or silver potential of the reaction mixture is controlled during the reaction may be preferably used.

**【0026】**

Other than the above, there are various approaches as the method for forming organic acid silver salt grains. To obtain organic acid silver salt grains, it is generally preferable to make solubility of the organic acid silver salt in the reaction field small. Further, according to the study of the inventors of the present invention, it has been revealed that the size of the formed organic acid silver salt grains becomes smaller as the addition time of the solution containing silver ions or the solution containing organic acid alkali metal salt becomes longer. In order to obtain organic acid silver salt grains in a desired size, the reaction time must be determined by try and error. Further, in the present invention, the reaction conditions are preferably controlled so that the concentration of the organic acid silver salt grains immediately after the reaction should become 1-10 weight %.

**【0027】**

The method of adding a solution of silver ion and a solution of an alkali metal salt of an organic acid is not specifically limited. Examples of such methods include adding the solutions onto the surface of the reaction mixture in reaction vessel, adding the solutions in the form of shower, adding the solutions through an outlet introduced into the reaction vessel, adding the solution from a separate room installed in the reaction vessel, adding the solution through a static type mixer installed in pipeline outside a tank, adding the solution to a separate vessel with a stirrer, and adding the solution to a mixer with a stirrer which is filled with reaction mixture and installed in pipeline outside the tank.

In the present invention, a silver salt of an organic acid may be prepared in any applicable reaction vessel batch-wisely or continuously. Agitation in the reaction vessel may be carried out by any means. Agitation means can be selected on the basis of the required characteristics of the grains. Examples of the agitation means include rotary stirrers and emulsification dispersion machines such as those provided with paddles and propellers, dissolvers and rotary homogenizers, static type mixers such as reciprocal motion type stirrers, static type mixers such as static mixers and throughother mixers, combinations thereof and so forth.

**【0028】**

In the sealed mixing means, a solvent (reaction field solution) can be placed beforehand prior to the addition of the solution containing silver ions or the solution containing organic acid alkali metal salt. While wafer is usually used as the solvent placed beforehand, a mixed solution with the organic solvent used for the solution containing silver ions and the solution containing organic acid alkali metal salt may also be used. Temperature of the liquid contained in the sealed mixing means is preferably 5°C to 70°C, more preferably 10°C to 50°C, most preferably 20°C to 45°C, in order to improve performance as a photographic photosensitive material. Throughout the entire process of the reaction, the reaction temperature is preferably controlled to be a constant temperature selected from the above-defined range. As the case may be, however, the reaction temperature may be controlled in some temperature profiles varying within the above-defined range.

**【0029】**

The temperature difference between the solution containing an alkali metal salt of an organic acid and the liquid in the sealed mixing means is preferably 20°C to 85°C, more preferably 30°C to 80°C. In this case, it is desirable that the temperature of the solution containing an alkali metal salt of an organic acid should be higher than that of the liquid contained in the sealed mixing means. By performing the process as described above, the rate at which the solution containing an alkali metal salt of an organic acid having a higher temperature is rapidly cooled by the reaction vessel and precipitated to give fine crystals, and the rate at which an organic acid silver salt is formed by the reaction with the water-soluble silver salt are both favorably controlled, and thereby the crystal morphology, crystal size and crystal size distribution of the organic acid silver salt can be favorably controlled. In addition, the properties of the thermally processed image recording material, in particular, photothermographic image recording material, can also be improved simultaneously.

**【0030】**

In order to prepare scaly silver salt of an organic acid preferred for the present invention, for example, when a solution containing silver ions is reacted with a tertiary alcohol aqueous solution containing an alkali metal salt of an organic acid in sealed mixing means (the method includes a step of adding the aqueous tertiary alcohol solution containing an alkali metal salt of an organic acid into a liquid contained in sealed mixing means), the temperature difference between the liquid already existing in the sealed mixing means and the aqueous tertiary alcohol solution of an alkali metal salt of an organic acid to be added thereto is controlled to be between 20°C and 85°C, wherein the liquid in the reaction vessel is a solution containing silver ions put into the reaction vessel in advance, or alternatively, the liquid is water or a mixed solvent of water and a tertiary alcohol in a case where the solution containing silver ions is not put into the reaction vessel in advance but is added from the beginning simultaneously with an aqueous solution of an alkali metal salt of an organic acid in a tertiary alcohol, and when the solution containing silver ions is put into the reaction vessel in advance, water or a mixed solvent of water and a tertiary alcohol may be placed in advance. By maintaining the temperature difference during the addition of the aqueous tertiary alcohol solution containing an alkali metal salt of an organic acid, the crystal morphology of the silver salt of an organic acid or the like can be favorably controlled. The tertiary alcohol may be added in any timing during the preparation of the organic acid silver salt. However, the tertiary alcohol is preferably added at the time of preparation of the organic acid alkali metal salt to dissolve the organic alkali metal salt. The tertiary alcohol may be added in any amount of from 0.01 to 10 as weight ratio based on the weight of water used as a solvent for the preparation of the organic acid silver salt, and preferably added in an amount of from 0.03 to 1.

**【0031】**

In the preparation methods of the present invention, as for the silver/alkali metal ratio after the reaction of the solution containing silver ions and the solution containing an alkali metal salt of an organic acid, it is preferred that the alkali should be excessive by 1–20 mole %, more preferably 1–10 mole %. Further, the concentration of the grains of organic acid silver salt immediately after the reaction is preferably 1–20 weight %, more preferably 1–10 weight %. The organic acid silver salt grains prepared by the methods of the present invention and used for the preparation of the thermally processed image recording material preferably have a diameter as sphere of 0.1–0.8 micrometers, more preferably 0.1–0.6 micrometers. Further, they preferably have a ratio of long side length/short side length of grains of 1–4, more preferably 1–3,

particularly preferably 1–2. Furthermore, the grains preferably have an aspect ratio (grain size for main plane (diameter as circle)/thickness of grain) of 2–30, more preferably 2–15. Further, the grains preferably have a thickness of is 0.01–0.20 micrometers, more preferably 0.01–0.15 micrometers. The grains are characterized by containing such grains satisfying the aforementioned requirements in an amount of 30–100%, more preferably 50–100%, particularly preferably 70–100%, in terms of a ratio to the projected area of total grains.

**[0032]**

The grain size distribution of the silver salt of an organic acid is preferably monodispersed one as far as possible. When a coefficient of variation is defined as a value 100 times as large as a value obtained by dividing the standard deviation of grain size by the grain size, the coefficient of variation is preferably 20% or less, more preferably 18% or less, further preferably 15% or less. As for the measurement method, for example, the grain size (volume weight average diameter) can be determined by irradiating silver salt of an organic acid dispersed in a liquid with a laser ray and determining an autocorrelation function of the fluctuation of the scattered light on the basis of the change in time (the so-called dynamic light scattering method).

**[0033]**

In a method for preparing an aqueous dispersion of grains of silver salt of an organic acid of the present invention, wherein grains of silver salt of an organic acid are prepared by reacting a solution containing silver ions and a solution containing an alkali metal salt of an organic acid, then dispersion operation is performed by a high pressure homogenizer or high speed rotary homomixer in the presence of a dispersing agent, and by-product salts are removed by ultrafiltration after or during the dispersion operation.

**[0034]**

In the methods of the present invention, a dispersing agent is preferably added to the system before the start of the reaction of the solution containing silver ions and the solution containing organic acid alkali metal salt or before ultrafiltration. The addition method is not particularly limited. For example, the dispersing agent may be contained in one to three kinds among the solution containing silver ions, the solution containing organic acid alkali metal salt and the solution put into the reaction vessel beforehand. The dispersing agent may also be added separately as a dispersing agent, or added as an additive comprising the dispersing agent and other components. When such a dispersing agent or additive is added, any one of water, organic solvent and mixture of water and an organic solvent may be used as a solvent. These addition methods may be used in any combination.

**[0035]**

The dispersing agent used in the present invention is preferably an anionic surfactant having a molecular weight of 3000 or less. The molecular weight is preferably 100–3000, more preferably 100–2000. The preferable anionic surfactant having a molecular weight of 3000 or less is an anionic surfactant which is soluble in water or a mixture of water and an organic acid (they may be referred as “aqueous medium”), is capable of dispersing a generated silver salt of an organic acid and has 8–40 carbon atoms, more preferably 12–40. The hydrophilic group may be any anionic group such as carboxylates, sulfuric acid ester salts, sulfonates and phosphoric acid ester salts. Preferable anionic groups are sulfuric acid ester salts and phosphoric acid ester salts, particularly those having an aromatic group, which impart an excellent dispersion stability under a high ionic strength with by-product salts produced by a reaction of a solution containing silver ion and a solution of alkali metal salt of an organic acid. Examples of the dispersing agents having a molecular weight of 3000 or less include sodium tetradecan-2,3-ene-1-sulfonate

(molecular weight 299), sodium diisobutyl naphthalenesulfonate, triisopropyl naphthalenesulfonic acid (molecular weight 357), and naphthalenesulfonic acid oligomer (average molecular weight 1,250), etc.

**[0036]**

The addition amount of the dispersing agent having a molecular weight of 3000 or less varies on, for example, types and grain size of the surfactant used. The amount of the above dispersing agent is not particularly limited so long as the produced silver salt of an organic acid does not aggregate. The amount is generally 0.1 to 30 weight %, preferably 1 to 30 weight %, more preferably 3 to 20 weight % of the dispersoid (the silver salt of an organic acid). To attain an absorption rate that is almost the same as the generation rate of the grains of silver salt of an organic acid, the amount of the dispersing agent is preferably 5 to 100 times, more preferably 20 to 80 times larger than the critical micelle concentration. As stated above, it is not specifically limited when the surfactant having a molecular weight of 3000 or less is introduced. Since the hydrophilic alkaline metal salt of an organic acid reacts with silver ion to form a hydrophobic silver salt of the organic acid whereby grains aggregate readily, it is preferable that the surfactant is introduced before completion of the addition of the solution containing silver ion.

**[0037]**

The dispersing agents having a molecular weight of more than 3000 can be also used. Such a dispersing agent can suitably be selected for use from known polymers, for example, synthetic anionic polymers such as polyacrylic acid, naphthalenesulfonic acid polymers, copolymers of acrylic acid, maleic acid copolymers, maleic acid monoester copolymers and copolymers of acryloylmethylpropane-sulfonic acid; semi-synthetic anionic polymers such as carboxymethyl starch and carboxymethyl cellulose; anionic polymers such as alginic acid and pectic acid; other polymers including polyvinyl alcohol (e.g., PVA-217 (trade name), mean polymerization degree: about 1700), polyvinylpyrrolidone, carboxymethyl cellulose, hydroxypropyl cellulose, hydroxy-propylmethyl cellulose etc., naturally occurring macromolecular compounds such as gelatin and so forth.

**[0038]**

In the present invention, a nonionic macromolecular dispersing agent is preferably used as a dispersing agent having a molecular weight of 3000 or more. More preferred is a nonionic macromolecular dispersing agent soluble in an aqueous reaction medium, which can disperse a silver salt of an organic acid and has a molecular weight of 5 times to 10 times the fractional molecular weight of an ultrafiltration membrane used for the desalting of the by-product salts produced from the reaction of the solution containing silver ions and the solution containing an alkali metal salt of an organic acid. As such a dispersing agent, polyvinyl alcohol, polyvinylpyrrolidone, hydroxyethyl cellulose and hydroxypropyl cellulose can preferably be used.

The concentration of the dispersing agent having a molecular weight of 3000 or more, preferably nonionic macromolecular dispersing agent is preferably 0.1-30 weight %, particularly preferably 0.5-30 weight %, of the silver salt of an organic acid. While the addition time of the dispersing agent having a molecular weight of 3000 or more, preferably nonionic macromolecular dispersing agent is not particularly limited, it is preferably added after completion of the reaction of the silver salt of an organic acid and before completion of the ultrafiltration operation in order to prevent inhibition of the reaction of the silver salt of an organic acid.

**[0039]**

The organic acid silver salt is extremely hydrophobic, and therefore, if the system does not contain a dispersing agent, crosslinking of the grains proceeds with time, and aggregation may

remarkably advance by a certain shearing field or pressure field during feeding operation or filtration through an ultrafiltration membrane described later. Further, in a strong ion strength environment before the desalting operation, surface charge of the organic acid silver salt grains is shielded, and hence they may be brought into a condition under which they are further likely to aggregate. In order to ameliorate this condition, it is desirable that pH is selected to be high so that dissociation of the species present on the grain surfaces should be accelerated. However, if the alkalinity in the environment becomes unduly high, the actions of silver oxide or reducing agent as impurity will be increased, and thus they cause fog. Therefore, in order to prevent the aggregation, pH of the dispersion must be maintained to be 6 or higher, preferably 6-8, until the electric conductivity reaches a level less than 2,000  $\mu\text{S}/\text{cm}$  and not less than 500  $\mu\text{S}/\text{cm}$  in the desalting operation by ultrafiltration. Even though a dispersing agent is used, pH of the dispersion is preferably controlled within this range.

**[0040]**

In the third preparation method of the present invention, the organic acid silver salt is dispersed as fine grains in the presence of a dispersing agent by using pulverization means. Examples of the pulverization means include high-speed mixer, homogenizer, high-speed impact mill, Banbury mixer, homomixer, kneader, ball mill, vibrating ball mill, planetary ball mill, attriter, sand mill, bead mill, colloid mill, jet mill, roller mill, trone mill, high-speed stone mill, high pressure homogenizer, ultrasonic dispersing machine and so forth. In the third preparation method of the present invention, at least high-pressure homogenizer or high-speed rotary type homomixer is used for dispersion.

**[0041]**

The high-pressure homogenizer is an apparatus for dispersing a dispersion system at a high pressure and high speed, in which large shearing force is applied to the dispersion system. Dispersion is attained with high pressure and high speed in a high pressure grinding section provided in the way of dispersion route, dispersion, emulsification and grinding are attained by passing a dispersion through a narrowed part of dispersion route at high pressure and high speed, or dispersions are collided with each other in a dispersion route.

As for the high-pressure homogenizer, it is generally considered that fine and uniform dispersion can be efficiently achieved therein by enhancing (a) "shear force" to be generated at the passage of a dispersoid through a narrow slit (75 micrometers to 350 micrometers or so) under high pressure at high speed and (b) "cavitation force" to be generated by the pressure releasing, but without changing the preceding impact force resulting from the liquid-liquid collision or the liquid-wall collision in the high-pressure narrow space. One old example of the dispersion apparatus of this type is a Golline homogenizer. In this apparatus, a liquid to be dispersed introduced under high pressure is converted into a high-speed flow when it is passed through a narrow gap formed on the wall of a cylindrical surface. Then, the flow collides against a surrounding wall with its own force, and is emulsified and dispersed by the impact force. For the liquid-liquid collision mentioned above, for example, there can be mentioned a Y-type chamber of Microfluidizer, a spherical chamber utilizing a spherical check valve such as that described in JP-A-8-103642 and so forth. For the liquid-wall collision, there can be mentioned a Z-type chamber of Microfluidizer and so forth. The pressure is generally 100 to 600  $\text{kg}/\text{cm}^2$ , and the flow rate is generally a few meters/sec to 30 meters/sec. In order to increase the dispersion efficiency, some apparatuses are designed wherein the high flow rate area is so modified as to have a serrated configuration, thereby increasing the frequency of collision. Typical examples of such apparatuses are Golline homogenizer (15MR-8TA produced by Golline, produced by APV),

High pressure homogenizer (produced by Izumi Food Machinery Co., Ltd.), Microfluidizer produced by Microfluidex International Corporation, Microfluidizer from Mizuho Kogyo Co., Ltd., Nanomizer from Tokushu Kika Kogyo Co., Ltd, Nanomizer LA53 produced by Nanomizer Co., Ltd., Nanomizer produced by Cosmo Keiso Co., Ltd, high pressure homogenizer such as Genus PY produced by Genus Co., Ltd. and so forth. Other examples of such apparatuses are described in JP-A-8-238848, JP-A-8-103642 and U.S. Patent No. 4,533,254.

In dispersing process of the organic acid silver salt, dispersion having a desired grain size may be obtained by controlling the flow rate, the difference in the pressure before and after at the pressure releasing and the frequency of the processing. The flow rate is preferably from 100 to 600 m/sec and the difference in pressure at the pressure releasing is preferably from 200 to 3,000 kg/cm<sup>2</sup>.

**【0042】**

Examples of high speed rotary type homomixer include high-speed shearing mixer produced by Tokushu Kika Kogyo Co., Ltd. (trade name: TK Homomixer), Milder MDN 303V produced by Ebara Corp. and so forth. While the rotation number may vary depending on capacity of dispersing machine, size of impellers and so forth, it is preferably about 1000-30000 rpm.

It is not preferable to expose such an aqueous dispersion to a high temperature under a high pressure in view of dispersibility and photographic performance. At a high temperature above 90°C, a grain size may readily become large and fog may be increased. Accordingly, the water dispersion is preferably kept at a temperature of from 5°C to 90°C, more preferably from 5°C to 80°C, particularly preferably from 5°C to 65°C, by a cooling step using a cooling apparatus during or after the dispersion in a high-pressure homogenizer or high-pressure rotary homomixer. The cooling apparatus may be appropriately selected from a double pipe or triple pipe with a static mixer, a multi-tubular heat exchanger, a coiled heat exchanger and so forth depending on an amount of heat exchange to be required. The size, wall thickness or material of pipes may be appropriately selected to increase heat exchange efficiency depending on an applied pressure. In addition, depending on an amount of heat exchange, a refrigerant used in the cooling apparatus may be a well water at 20°C or a chilled water at from 5 to 10°C cooled by a refrigerator, and if desired, a refrigerant such as ethylene glycol/water at -30°C may also be used.

**【0043】**

Further, in the third preparation method of the present invention, ultrafiltration is performed after or during the aforementioned dispersion operation. As the method for ultrafiltration performed in the present invention, methods used for desalting and concentration of silver halide emulsion, and for example, those methods described in Research Disclosure, No. 10208 (1972), No. 13122 (1975), No. 16351 (1977) etc. can be used. While pressure difference and flow rate, which are important as the operational conditions, can be selected by referring to the characteristic curves mentioned in Haruhiko Oya, "Maku Riyo Gijutsu Handbook (Membrane Utilization Technique Handbook)", published by Saiwai Shobo (1978), p.275, it is necessary to find out optimum conditions for treating an organic acid silver salt dispersion of interest in order to suppress aggregation of grains, fog and so forth. As an ultrafiltration membrane, modules of plate type, spiral type, cylinder type, hollow yarn type, hollow fiber type and so forth, in which a membrane is already incorporated, are commercially available from Asahi Chemical Industry Co., Ltd., Daicel Chemical Industries, Ltd., Toray Industries, Inc., NITTO DENKO CORP. and so forth. In view of the total membrane area, washability and so forth, those of hollow yarn type and spiral type are preferred. Examples of the material of ultrafiltration membrane include polysulphone, polyphenyl sulphone, polyether sulphone, polyacrylonitrile and so forth, and examples of module

type include flat membrane, hollow yarn membrane, tubular membrane and so forth. The fractional molecular weight, which is an index of a threshold for substances that can permeate a membrane, must be determined based on the molecular weight of the used dispersing agent. In the present invention, those having a fractional molecular weight of 1,500–50,000, more preferably 4,000–50,000, are preferably used.

**[0044]**

In the present invention, it is preferable to perform the desalting treatment after the organic acid silver salt grains immediately after the reaction is concentrated to a concentration of 15–40 weight %, preferably 15–25 weight %. Further, the liquid temperature after the grain formation is preferably kept low until the desalting operation proceeds. This is because silver nuclei are likely to be formed by the shearing force field and the pressure field during the feeding of dispersion or passage through an ultrafiltration membrane under a condition that the solvent used for dissolving the alkali metal salt of an organic acid permeates in the produced organic acid silver salt grains. For this reason, in the present invention, the ultrafiltration operation is desirably performed while the temperature of the organic acid silver salt grain dispersion is kept at 1–30°C, preferably at 5–25°C.

**[0045]**

As a method for supplementing the solvent lost due to passage through the membrane, there may be employed either the constant volume method where the solvent is continuously supplemented, or the batch method where the solvent is intermittently added. The constant volume method is preferred in the present invention because of its relatively shorter desalting treatment time. The solvent to be supplemented as described above comprises pure water obtained by ion exchange or distillation, which may contain a pH modifier. However, if the desalting operation is performed by dilution with pure water during the ultrafiltration operation, the concentration of the dispersing agent is reduced and hence aggregation may be caused. Therefore, a surfactant is preferably supplemented in order to maintain a certain level of surfactant concentration to prevent the aggregation. In particular, because the organic acid silver salt grains are in a state that they are likely to aggregate in the high salt concentration circumstance of the early stage of the desalting operation with the presence of an organic solvent such as tertiary alcohol, the concentration of anionic surfactant, for example, is preferably maintained at a level 5 to 100 times as high as the critical micelle concentration. Specifically, while the concentration of leaking surfactant is quantified by spectrophotometry or liquid chromatography, a solution having the same concentration as the measured concentration may be continuously added as a replenisher, or a solution having a concentration higher than that may be added intermittently.

**[0046]**

Further, since the silver salt of an organic acid is extremely hydrophobic, aggregation may markedly proceed under a shearing field or pressure field during the feeding operation and passage through an ultrafiltration membrane. Furthermore, in a high ionic strength circumstance in early stages of the desalting operation, the surface charge of the organic acid silver salt grains is shielded, and hence they become more likely to aggregate. In order to ameliorate this condition, when an anionic surfactant is added in advance, another ionic surfactant having anionic nature and a hydrophobic group with 8–40 carbon atoms different from the anionic surfactant added beforehand may be added during the desalting operation. As for the addition method, while the concentration of leaking surfactant is quantified by spectrophotometry or liquid chromatography, a solution having the same concentration as the measured concentration may

be continuously added, or a solution having a concentration higher than that may be added intermittently, as described above.

**[0047]**

If the fractional molecular weight of an ultrafiltration membrane is unknown, its rejection can be obtained by filtering a solution of a dispersing agent to be used, and calculating the rejection from the concentration of the surfactant leaked into the filtrate. When a surfactant is used, the rejection  $R$  of an ultrafiltration membrane is defined by the following equation:

$$R = (C_i - C_o)/C_i \times 100 [\%]$$

wherein  $C_i$  represent a concentration in original dispersion, and  $C_o$  represents a leaked concentration in the filtrate. The rejection is preferably less than 50% for the methods of the present invention.

**[0048]**

In a preferred embodiment, a dispersing agent having a molecular weight of more than 3,000, preferably a nonionic macromolecular dispersing agent may be added after the desalting is performed by ultrafiltration and thus electric conductivity of the organic acid silver salt dispersion is lowered, but before completion of the desalting operation. At this time, the conductivity is preferably 2000  $\mu\text{S}/\text{cm}$  or less. In this case, in order to remove anionic surfactant having a molecular weight of 3,000 or less and replace it with a dispersing agent having a molecular weight of more than 3,000, preferably a nonionic macromolecular dispersing agent, there is preferably performed an operation of adding pure water in an amount corresponding to the amount of the anionic surfactant solution passed through the ultrafiltration membrane, i.e., the so-called constant volume dilution, in an order of 2- to 20-fold.

**[0049]**

In the present invention, it is also possible to carry out the ultrafiltration operation while adding a poor solvent for the dispersing agent used after the conductivity has reached a level below 1,000  $\mu\text{S}/\text{cm}$  with the progress of the desalting. Under a low ionic strength circumstance, aggregation is not caused even if the protection effect of the dispersing agent is reduced, because stabilizing effect is exerted by electric charge on the grain surfaces. In addition, the viscosity of the whole dispersion becomes high due to increase of repulsion between the grains, and therefore the filtration operation becomes difficult. In order to avoid this phenomenon, it is desirable to add the poor solvent for the dispersing agent.

**[0050]**

After the removal of by-product salts by ultrafiltration, the dispersion can be further concentrated by ultrafiltration. In particular, after the electric conductivity comes to be 20  $\mu\text{S}/\text{cm}$  or more to less than 300  $\mu\text{S}/\text{cm}$  due to the removal of by-product salts by the ultrafiltration, the dispersion can be preferably concentrated to a concentration of 10-70 weight %, more preferably 20-50 weight %.

**[0051]**

In the present invention, metal ions selected from Ca, Mg, Ce, Al, Zn and Ba are preferably added in the form of a water-soluble metal salt, which is not a halide compound. Specifically, they are preferably added in the form of nitrate or sulfate. Time of the addition of the metal ions selected from Ca, Mg, Ce, Al, Zn and Ba is not particularly limited, and they may be added any time. For example, they may be added to a liquid of organic acid silver salt preparation, preliminarily added to a reaction mixture, added during or immediately after the formation of the organic acid silver salt, or immediately before the coating, i.e., before or after the formation of coating solution. The amount is preferably  $10^{-3}$  to  $10^{-1}$  mole, particularly preferably

$5 \times 10^{-3}$  to  $5 \times 10^{-2}$  mole, per one mole of the organic acid silver salt.

[0052]

When a photosensitive silver halide salt coexists at the time of finely dispersing the silver salt of an organic acid by converting the dispersion into a high-speed flow under a high pressure, fog may increase and sensitivity may markedly decrease. The amount of photosensitive silver halide salt in an aqueous dispersion is 0.1 mole % less per 1mole of silver salt of organic acid. It is desirable that a photosensitive silver halide salt is not added positively.

[0053]

The prepared dispersion can be stored with stirring to prevent precipitation of the grains during storage, or stored in a highly viscous state formed by means of hydrophilic colloids (e.g., a jelly state formed with gelatin). Furthermore, the dispersion may contain a preservative in order to prevent proliferation of microorganisms during storage. The silver salt of an organic acid solid fine grain dispersion used in the present invention comprises at least a silver salt of an organic acid and water. While the ratio of the silver salt of an organic acid to water is not particularly limited, it must be decided based on rheological characteristics for stable coating and production speed determined by dry moisture content in view of efficient formation of coated films. The silver salt of an organic acid preferably accounts for from 10-70 weight %, particularly preferably from 20-50 weight % of the entire dispersion.

[0054]

The dispersion of organic acid silver salt grains prepared by the preparation methods of the present invention is preferably finely dispersed in an aqueous solvent, and then mixed with an aqueous solution of a photosensitive silver halide salt to provide a coating solution for photosensitive image-forming layer of a photothermographic material. Such a coating solution enables the manufacture of a thermally processed image recording material exhibiting low haze and low fog, and showing high sensitivity. When a photosensitive silver halide salt coexists at the time of finely dispersing the silver salt of an organic acid by converting the dispersion into a high-speed flow under a high pressure, fog may increase and sensitivity may markedly decrease. Therefore, the aqueous dispersion that is dispersed by converting it into a high-speed flow under high pressure preferably contains substantially no photosensitive silver halide salt. Furthermore, when an organic solvent is used as a dispersion medium instead of water, haze and fog may increase and sensitivity may be likely to decrease. On the other hand, when the conversion method where a part of the silver salt of an organic acid in the dispersion is converted into a photosensitive silver halide salt is used instead of the method of mixing an aqueous photosensitive silver halide salt solution, sensitivity may be decreased.

[0055]

The shape of the silver salt of an organic acid that can be used for a thermally processed image recording material, in particular, photothermographic material, is not particularly limited, and scaly grains, acicular grains, rod-like grains and tabular grains can be mentioned. However, scaly silver salt of an organic acid is preferred. Scaly silver salt of an organic acids are herein defined as follows. A sample of a silver salt of an organic acid to be analyzed is observed with an electronic microscope, and grains of the salt seen in the field are approximated to rectangular parallelepipeds. The three different edges of each rectangular parallelepiped are represented as a, b and c where a is the shortest, c is the longest, and c and b may be the same. From the shorter edges a and b, x is obtained according to the following equation:

$$x = b/a$$

The values of x are obtained for about 200 grains, and an average of them (x (average)) is

obtained. Samples that satisfy the requirement of  $x$  (average)  $\geq 1.5$  are defined to be scaly. Scaly grains preferably satisfy  $30 \geq x$  (average)  $\geq 1.5$ , more preferably  $20 \geq x$  (average)  $\geq 2.0$ . In this connection, acicular (needle-like) grains falls satisfy  $1 \leq x$  (average)  $< 1.5$ .

**【0056】**

In scaly grains, it is understood that  $a$  corresponds to the thickness of tabular grains of which main planes are defined by the sides of  $b$  and  $c$ . The average of  $a$  is preferably from 0.01 to 0.23 micrometers, more preferably from 0.1 to 0.20 micrometers. The average of  $c/b$  is preferably from 1 to 6, more preferably from 1.05 to 4, even more preferably from 1.1 to 3, particularly preferably from 1.1 to 2.

**【0057】**

The organic acid silver salt grains prepared by the methods of the present invention and used for the preparation of the thermally processed image recording material preferably have a diameter as sphere of 0.1–0.8 micrometers, more preferably 0.1–0.6 micrometers. Further, they preferably have a ratio of long side length/short side length of grains of 1–4, more preferably 1–3, particularly preferably 1–2. Furthermore, the grains preferably have an aspect ratio (grain size for main plane (diameter as circle)/thickness of grain) of 2–30, more preferably 2–15. Further, the grains preferably have a thickness of is 0.01–0.20 micrometers, more preferably 0.01–0.15 micrometers. The grains are characterized by containing such grains satisfying the aforementioned requirements in an amount of 30–100%, more preferably 50–100%, particularly preferably 70–100%, in terms of a ratio to the projected area of total grains.

**【0058】**

The grain size distribution of the silver salt of an organic acid is preferably monodispersed one as far as possible. When a coefficient of variation is defined as a value 100 times as large as a value obtained by dividing the standard deviation of grain size by the grain size, the coefficient of variation is preferably 20% or less; more preferably 18% or less, further preferably 15% or less. As for the measurement method, for example, the grain size (volume weight average diameter) can be determined by irradiating silver salt of an organic acid dispersed in a liquid with a laser ray and determining an autocorrelation function of the fluctuation of the scattered light on the basis of the change in time (the so-called dynamic light scattering method).

**【0059】**

The grain size (volume weight average diameter) in an organic acid silver salt solid dispersion can be obtained from a grain size (volume weight average diameter) determined by, for example, irradiating silver salt of an organic acid dispersed in a liquid with a laser ray and determining an autocorrelation function of the fluctuation of the scattered light on the basis of the change in time. Preferred is a solid fine grain dispersion having a mean grain size of 0.05 to 10.0 micrometers, more preferably from 0.1 to 5.0 micrometers, further preferably from 0.1 to 2.0 micrometers.

**【0060】**

The mixing ratio of the photosensitive silver halogenate to the silver salt of an organic acid can be determined based on the purpose of the thermally processed image recording material. The ratio is preferably 1 to 30 mole %, more preferably 3 to 20 mole %, particularly preferably 5 to 15 mole %. In order to control the photographic properties, it is preferable to mix two or more aqueous dispersions of a silver salt of an organic acid with two or more aqueous dispersions of photosensitive silver halide.

The silver salt of an organic acid may be used in any desired amount in the thermally processed image recording material. However, it is preferably used in an amount of 0.1–5 g/m<sup>2</sup>, more preferably 1–3 g/m<sup>2</sup>, in terms of silver amount.

【0061】

The thermally processed image recording material utilizing the organic acid silver salt grains prepared by the methods of the present invention preferably contains a reducing agent for the organic acid silver salt. The reducing agent for the organic acid silver salt may be any substance (preferably, organic substance) capable of reducing silver ions into silver. Some examples of the reducing agent are described in JP-A-11-65021, paragraphs 0043 to 0045, EP 0803764A1, from page 7, line 34 to page 18, line 12, Japanese Patent Application Nos. 2000-16661, 2000-208 and 2000-2428.

Especially preferred are bisphenol-type reducing agents, and preferred examples thereof are mentioned below, but not limited to these.

#### 【0067】

The amount of the reducing agent is preferably 0.01–5.0 g/m<sup>2</sup>, more preferably 0.1–3.0 g/m<sup>2</sup>. The amount of the reducing agent is preferably 5–50 mole %, more preferably 10–40 mole %, per mole of silver on the image-forming layer side. The reducing agent is preferably contained in the image-forming layer. The reducing agent may be added to a coating solution in any form such as solution, emulsion dispersion and solid microparticle dispersion, so as to be contained in the thermally processed image recording material. As a well known emulsion dispersion method, there can be mentioned a method for mechanically preparing an emulsion dispersion by using an oil such as dibutyl phthalate, tricresyl phosphate, glyceryl triacetate or diethyl phthalate, ethyl acetate or cyclohexanone as an auxiliary solvent for dissolution.

#### 【0068】

Further, as a method for solid microparticle dispersion, there can be mentioned a method for preparing solid microparticle dispersion by dispersing powder of the reducing agent in a suitable solvent such as water using a ball mill, colloid mill, vibration ball mill, sand mill, jet mill and roller mill, or by means of ultrasonic wave. In this operation, protective colloid (e.g., polyvinyl alcohol), surfactant (e.g., anionic surfactants such as sodium triisopropyl naphthalenesulfonate (mixture of those having three isopropyl groups on different positions)) and so forth may be used. An aqueous dispersion may contain a preservative (e.g., benzisothiazolinone sodium salt).

**[0069]**

In the thermally processed image recording material, the phenol derivatives represented by the formula (A) mentioned in Japanese Patent Application No. 11-73951 are preferably used as a development accelerator.

**[0070]**

When the reducing agent has an aromatic hydroxyl group ( $-OH$ ), in particular when the reducing agent is any of the aforementioned bisphenols, it is preferable to use together a non-reducing compound having a group that can form a hydrogen bond with the aromatic hydroxyl group. Examples of the group that can form a hydrogen bond with hydroxyl group or amino group include phosphoryl group, sulfoxido group, sulfonyl group, carbonyl group, amido group, an ester group, urethane group, ureido group, a tertiary amino group, a nitrogen-containing aromatic group and so forth. Particularly preferred examples of such a compound are those compounds having phosphoryl group, sulfoxido group, amido group (provided that it does not have  $>N-H$  group, but it is blocked like  $>N-R$  ( $R$  is a substituent other than  $H$ )), urethane group (provided that it does not have  $>N-H$  group, but it is blocked like  $>N-R$  ( $R$  is a substituent other than  $H$ )), or ureido group (provided that it does not have  $>N-H$  group, but it is blocked like  $>N-R$  ( $R$  is a substituent other than  $H$ )). Particularly preferred hydrogen bond-forming compounds are compounds represented by the following formula (II).

**[0071]**

**[Chemical formula 6]**

**[0072]**

In the formula (II),  $R^{11}$ ,  $R^{12}$  and  $R^{13}$  each independently represent an alkyl group, an aryl group, an alkoxy group, an aryloxy group, an amino group or a heterocyclic group, and these groups may or may not have one or more substituents. Two of  $R^{11}$ ,  $R^{12}$  and  $R^{13}$  may be bonded together to form a ring.

When  $R^{11}$ ,  $R^{12}$  and  $R^{13}$  have one or more substituents, they can be selected from a halogen atom, an alkyl group, an aryl group, an alkoxy group, an amino group, an acyl group, an acylamino group, an alkylthio group, an arylthio group, a sulfonamide group, an acyloxy group, an oxycarbonyl group, a carbamoyl group, a sulfamoyl group, a sulfonyl group, a phosphoryl group and so forth, and they are preferably selected from an alkyl group and an aryl group. Specific examples thereof are methyl group, ethyl group, isopropyl group, *t*-butyl group, *t*-octyl group, phenyl group, 4-alkoxyphenyl group, 4-acyloxyphenyl group and so forth.

**[0073]**

Specific examples of the groups represented by  $R^{11}$ ,  $R^{12}$  and  $R^{13}$  include a substituted or unsubstituted alkyl group such as methyl group, ethyl group, butyl group, octyl group, dodecyl group, isopropyl group, *t*-butyl group, *t*-amyl group, *t*-octyl group, cyclohexyl group, 1-methylcyclohexyl group, benzyl group, phenethyl group and 2-phenoxypropyl group; a substituted or unsubstituted aryl group such as phenyl group, cresyl group, xylyl group, naphthyl group, 4-*t*-butylphenyl group, 4-*t*-octylphenyl group, 4-anisidyl group and 3,5-dichlorophenyl

group; a substituted or unsubstituted alkoxyl group such as methoxy group, ethoxy group, butoxy group, octyloxy group, 2-ethylhexyloxy group, 3,5,5-trimethylhexyloxy group, dodecyloxy group, cyclohexyloxy group, 4-methylcyclohexyloxy group and benzyloxy group; a substituted or unsubstituted aryloxy group such as phenoxy group, cresyloxy group, isopropylphenoxy group, 4-t-butylphenoxy group, naphthoxy group and biphenyloxy group; a substituted or unsubstituted amino group such as amino group, dimethylamino group, diethylamino group, dibutylamino group, dioctylamino group, N-methyl-N-hexylamino group, dicyclohexylamino group, diphenylamino group and N-methyl-N-phenylamino group; a heterocyclic group such as 2-pyridyl group, 4-pyridyl group, 2-furanyl group, 4-piperidinyl group, 8-quinolyl group and 5-quinolyl group, and so forth.

**[0074]**

$R^{11}$ ,  $R^{12}$  and  $R^{13}$  are preferably selected from an alkyl group, an aryl group, an alkoxy group and an aryloxy group. It is preferred that one or more of  $R^{11}$ ,  $R^{12}$  and  $R^{13}$  should be selected from an alkyl group and an aryl group, and it is more preferred that two or more of  $R^{11}$ ,  $R^{12}$  and  $R^{13}$  should be selected from an alkyl group and an aryl group. In view of availability at low cost, it is preferred that  $R^{11}$ ,  $R^{12}$  and  $R^{13}$  should be the same groups.

**[0075]**

Specific examples of the compound represented by the formula (II) will be shown below. However, the compounds that can be used for the present invention are not limited to these examples.

【0080】

The compound represented by the formula (II) may be added to a coating solution, like the reducing agent, in the form of solution, emulsion dispersion or solid microparticle dispersion for use in the thermally processed image recording material. The compound represented by the formula (II) forms a complex in a solution with a compound having a phenolic hydroxyl group or amino group through hydrogen bond, and hence it can be isolated as crystals of such a complex

depending on the combination of the reducing agent and the compound represented by the formula (II). Crystal powder isolated in such a manner is particularly preferably used as solid microparticle dispersion in order to obtain stable performance. Further, it is also preferable to mix the reducing agent and the compound represented by the formula (II) as powders and allow them to form a complex during dispersion operation using a suitable dispersing agent in a sand grinder mill or the like. The compound represented by the formula (II) is preferably used in an amount of 1–200 mole %, more preferably 10–150 mole %, further preferably 30–100 mole %, with respect to the reducing agent.

**[0081]**

The photosensitive silver halide that can be used for the present invention is not particularly limited as for the halogen composition, and silver chloride, silver chlorobromide, silver bromide, silver iodobromide, and silver chloriodobromide may be used. The halide composition may have a uniform distribution in the grains, or the compositions may change stepwise or continuously in the grains. Silver halide grains having a core/shell structure may be preferably used. Core/shell grains having preferably a double to quintuple structure, more preferably a double to quadruple structure may be used. A technique for localizing silver bromide on the surface of silver chloride or silver chlorobromide grains may also be preferably used.

**[0082]**

Methods for the preparation of the photosensitive silver halide are well known in the art, and there can be used, for example, the methods described in Research Disclosure, No. 17029 (June, 1978) and U.S. Patent No. 3,700,458. More specifically, a method can be used which comprises preparing photosensitive silver halide grains by addition of a silver-supplying compound and a halogen-supplying compound to a solution of gelatin or other polymer, and then mixing the resulting grains with a silver salt of an organic acid. The methods disclosed in JP-A-119374, paragraphs 0217 to 0224, Japanese Patent Application Nos. 11-98708 and 11-84182 are also preferred.

**[0083]**

As for a grain size of the photosensitive silver halide, smaller grains are desirable to prevent cloudiness after image formation. Specifically, the grain size may preferably be not greater than 0.20 micrometers, more preferably 0.01–0.15 micrometers, further preferably 0.02–0.12 micrometers. The term “grain size” used herein means a diameter of a projected area of sphere having the same volume as the grain (where silver halide grains are tabular grains, the term means the diameter of a circle having the same area as a projected area of the main surface of the tabular grain).

**[0084]**

Examples of the form of silver halide grains include a cubic form, octahedral form, tabular form, spherical form, rod-like form and potato-like form. In particular, cubic grains are preferred. Silver halide grains having round corners are also preferably used. Surface index (Miller index) of outer surfaces of the photosensitive silver halide grains is not particularly limited. However, it is desirable that the [100] face should be present in a high proportion that can achieve high spectral sensitizing efficiency when a spectral sensitizing dye adsorbs on the grains. The proportion of the [100] face may be preferably not lower than 50%, more preferably at least 65%, still more preferably at least 80%. The proportion of Miller index [100] face can be determined using the method described in T. Tani, J. Imaging Sci., 29, 165 (1985), which utilizes the difference in adsorption of a sensitizing dye to [111] face and [100] face.

**[0085]**

Silver halide grains having hexacyano-metal complex on their outermost surfaces are preferably used. Specific examples of the hexacyano-metal complex include  $[\text{Fe}(\text{CN})_6]^{4-}$ ,  $[\text{Fe}(\text{CN})_6]^{3-}$ ,  $[\text{Ru}(\text{CN})_6]^{4-}$ ,  $[\text{Os}(\text{CN})_6]^{4-}$ ,  $[\text{Co}(\text{CN})_6]^{3-}$ ,  $[\text{Rh}(\text{CN})_6]^{3-}$ ,  $[\text{Ir}(\text{CN})_6]^{3-}$ ,  $[\text{Cr}(\text{CN})_6]^{3-}$ ,  $[\text{Re}(\text{CN})_6]^{3-}$  and so forth. In the present invention, hexacyano-Fe complexes are preferred.

**[0086]**

Since the hexacyano-metal complex exists in the form of an ion in an aqueous solution, its counter cation is not critical. However, it is preferable to use ions readily mixed with water and suitable for the precipitation operation of silver halide emulsions, for example, alkali metal ions such as sodium ion, potassium ion, rubidium ion, cesium ion and lithium ion, ammonium ions, alkylammonium ions (e.g., tetramethylammonium ions, tetraethylammonium ions, tetrapropylammonium ions, tetra-(n-butyl)ammonium ions) and so forth.

**[0087]**

The hexacyano-metal complex may be added to silver halide grains in the form of a solution in water or in a mixed solvent of water and an organic solvent miscible with water (for example, alcohols, ethers, glycols, ketones, esters, amides etc.), or in the form of a mixture thereof with gelatin.

**[0088]**

The amount of the hexacyano-metal complex is preferably  $1 \times 10^{-5}$  mole to  $1 \times 10^{-2}$  mole, more preferably  $1 \times 10^{-4}$  mole to  $1 \times 10^{-3}$  mole, per mol of silver.

**[0089]**

In order to make the hexacyano-metal complex exist on the outermost surfaces of silver halide grains, the hexacyano-metal complex is directly added before completion of the grain formation process, i.e., after the addition of an aqueous silver nitrate solution used for the formation of silver halide grains and before chemical sensitization process where chalcogen sensitization with sulfur, selenium or tellurium or noble metal sensitization with gold or the like is performed, during washing with water or dispersion operation or immediately before the chemical sensitization. To prevent growth of the silver halide grains, it is desirable that the hexacyano-metal complex is added to the grains immediately after the grains are formed, and the complex is added before the grain formation process is finished.

**[0090]**

The addition of the hexacyano-metal complex may be started after 96 weight % of the total of silver nitrate for grain formation has been added. More preferably, it is added after 98 weight of silver nitrate, particularly preferably after 99 weight % of silver nitrate has been added.

**[0091]**

If the hexacyano-metal complex is added after addition of aqueous solution of silver nitrate in which the formation of silver halide grains is almost completed, the hexacyano-metal complex can be adsorbed onto the outermost surfaces of the silver halide grains, and most of the complex forms a hardly-soluble salt with silver ions existing on the surfaces of the grains. Such a silver salt of hexacyano-iron(II) is a salt more hardly soluble than AgI, and therefore fine grains formed are prevented from being dissolved again. Thus, it becomes possible to produce fine silver halide grains having a small grain size.

**[0092]**

The photosensitive silver halide grains may contain a metal of Group VIII to Group X in the periodic table of elements (including Group I to Group XVIII) or metal complex thereof. The metal of Group VIII to X of the periodic table or the center metal of the metal complex is preferably rhodium, ruthenium or iridium. The metal complex may be used alone, or two or more complexes of

the same or different metals may also be used in combination. The metal complex content is preferably from  $1 \times 10^{-8}$  to  $1 \times 10^{-3}$  mole per mole of silver. Such heavy metals and metal complexes as well as addition method therefor are described in JP-A-7-225449, JP-A-11-65021, paragraphs 0018 to 0024, and JP-A-11-119374, paragraphs 0227 to 0240.

**[0093]**

Further, metal complexes that can be contained in the silver halide grains used for the present invention (e.g.,  $[\text{Fe}(\text{CN})_6]^{4-}$ ), desalting methods and chemical sensitization methods are described in JP-A-11-84574, paragraphs 0046 to 0050, JP-A-11-65021, paragraphs 0025 to 0031, and JP-A-11-119374, paragraphs 0242 to 0250.

**[0094]**

As gelatin contained in the photosensitive silver halide emulsion, various kinds of gelatin may be used. In order to obtain good dispersion state of the photosensitive silver halide emulsion in a coating solution containing a silver salt of an organic acid, low molecular weight gelatin having a molecular weight of 500-60,000 is preferably used. While such low molecular weight gelatin may be used during the grain formation or the dispersion operation after the desalting treatment, it is preferably used during the dispersion operation after the desalting treatment.

**[0095]**

As a sensitizing dye that can be used for the present invention, there can be advantageously selected those sensitizing dyes which can spectrally sensitize silver halide grains within a desired wavelength range after they are adsorbed by the silver halide grains and have spectral sensitivity suitable for spectral characteristics of the light source to be used for exposure. Such sensitizing dyes and addition methods therefor are described in JP-A-11-65021, paragraphs 0103 to 0109, JP-A-10-18657 as for the compounds represented by the formula (II), JP-A-11-119347 as for the dyes represented by the formula (I) and paragraph 0106, U.S. Patent Nos. 5,510,236, 3,871,887 as for the dyes disclosed in Example 5, JP-A-2-96131, JP-A-59-48753 as for the dyes disclosed therein and EP 0803764A1, page 19, line 38 to page 20, line 35, Japanese Patent Application Nos. 2000-86865, 2000-102560 and so forth. These dyes may be used each alone or in any combination of two or more of them. The sensitizing dye is added to the silver halide emulsion preferably during the period after the desalting step and before the coating step, more preferably during the period after the desalting step and before the start of the chemical ripening.

While the amount of the sensitizing dye used in the present invention may be selected to be a desired amount depending on the performance including sensitivity and fog, it is preferably  $10^{-6}$  to 1 mole, more preferably  $10^{-4}$  to  $10^{-1}$  mole, per mole of silver halide in the image-forming layer.

**[0096]**

A supersensitizer can be used for the thermally processed image recording material in order to improve spectral sensitization efficiency. Examples of the supersensitizer include the compounds disclosed in EP587338A, U.S. Patent Nos. 3,877,943, 4,873,184, JP-A-5-341432, JP-A-11-109547, JP-A-10-111543 and so forth.

**[0097]**

Photosensitive silver halide grains are preferably subjected to chemical sensitization by sulfur sensitization, selenium sensitization or tellurium sensitization. Any known compounds can be preferably used for such sulfur, selenium or tellurium sensitization, and for example, the compounds described in JP-A-7-128768 and so forth are usable for that purpose. Tellurium

sensitization is particularly preferred, and the compounds described in JP-A-11-65021, paragraph 0030 and the compounds of formulas (II), (III) and (IV) given in JP-A-5-313284 are more preferred.

**[0098]**

The chemical sensitization may be performed at any time so long as it is performed after the formation of the grains and before the coating. It may be performed after desalting and (1) before the spectral sensitization, (2) simultaneously with the spectral sensitization, (3) after the spectral sensitization, (4) immediately before the coating, or the like.

It is particularly preferably performed after spectral sensitization. The amount of the sulfur, selenium or tellurium sensitizer varies depending on the type of the silver halide grains to be used, the condition for chemical ripening etc., but may fall generally between  $10^{-8}$  and  $10^{-2}$  mole, preferably between  $10^{-7}$  and  $10^{-3}$  mole or so, per mol of the silver halide. Although the conditions for the chemical sensitization are not particularly limited, in general, pH is in the range of 5-8, the pAg in the range of 6-11, and the temperature in the range of 40-95°C.

**[0099]**

The silver halide emulsion may be added with a thiosulfonic acid compound according to the method disclosed in EP293917A.

**[0100]**

In the thermally processed image recording material, one kind of photosensitive silver halide emulsion may be used or two or more different emulsions (for example, those having different average grain sizes, different halogen compositions, different crystal habits or different chemical sensitization conditions) may be used in combination. By using plural photosensitive silver halides having different sensitivities, contrast can be controlled. Examples of the techniques concerning this respect include those mentioned in JP-A-57-119341, JP-A-53-106125, JP-A-47-3929, JP-A-48-55730, JP-A-46-5187, JP-A-50-73627, JP-A-57-150841 and so forth. Each emulsion preferably has sensitivity difference of 0.2 log E or higher for other emulsions.

**[0101]**

The amount of the photosensitive silver halide is preferably 0.03-0.6 g/m<sup>2</sup>, more preferably 0.05-0.4 g/m<sup>2</sup>, most preferably 0.1-0.4 g/m<sup>2</sup>, as the amount of coated silver per 1 m<sup>2</sup> of the thermally processed image recording material. The amount of the photosensitive silver halide per mole of the silver salt of an organic acid is preferably from 0.01-0.5 mole, more preferably from 0.02-0.3 mole.

**[0102]**

Methods and conditions for mixing photosensitive silver halide and a silver salt of an organic acid, which are separately prepared, are not particularly limited so long as the effect of the present invention can be attained satisfactorily. Examples thereof include, for example, a method of mixing silver halide grains and a silver salt of an organic acid after completion of respective preparations by using a high-speed stirring machine, ball mill, sand mill, colloid mill, vibrating mill, homogenizer or the like, or a method of preparing a silver salt of an organic acid by mixing a photosensitive silver halide obtained separately at any time during the preparation of the silver salt of an organic acid. For the mixing of them, mixing two or more kinds of aqueous dispersions of the silver salt of an organic acid and two or more kinds of aqueous dispersions of the photosensitive silver salt is preferably used for controlling photographic properties.

**[0103]**

Preferred addition time point for the silver halide into the coating solution for image-forming layer resides in a period of from 180 minutes before the coating to immediately before the coating, preferably 60 minutes to 10 seconds before the coating. However, the

method and conditions for mixing are not particularly limited. Specific examples of the mixing method include a method in which the mixing is performed in a tank designed so that a desired average residence time therein can be obtained, which residence time is calculated from addition flow rate and feeding amount to a coater, a method utilizing a static mixer described in N. Hamby, M.F. Edwards, A.W. Nienow, "Ekitai Kongo Gijutsu (Techniques for Mixing Liquids)", translated by Koji Takahashi, Chapter 8, Nikkan Kogyo Shinbunsha, 1989 and so forth.

**[0104]**

The binder of the layer containing the silver salt of an organic acid may be any polymer. Preferred binders are those that are transparent or translucent, and generally colorless. The binder may consist of, for example, a naturally occurring resin, polymer or copolymer, synthetic resin, polymer or copolymer or other media that can form a film, such as gelatins, rubbers, poly(vinyl alcohols), hydroxyethyl celluloses, cellulose acetates, cellulose acetate butyrates, poly(vinylpyrrolidones), casein, starch, poly(acrylic acids), poly(methyl methacrylates), poly(vinyl chlorides), poly(methacrylic acids), styrene/maleic anhydride copolymers, styrene/acrylonitrile copolymers, styrene/butadiene copolymers, poly(vinyl acetals) (e.g., poly(vinyl formal), poly(vinyl butyral)), poly(esters), poly(urethanes), phenoxy resin, poly(vinylidene chlorides), poly(epoxides), polycarbonates, poly(vinyl acetates), poly(olefins), cellulose esters and poly(amides). The binder may be formed from water, organic solvent or emulsion by coating it.

**[0105]**

If the layer containing the silver salt of an organic acid is formed by using an aqueous coating solution containing 30 weight % or more of water based on a total solvent, further, if the binder of the layer containing the silver salt of an organic acid is soluble or dispersible in an aqueous solvent (water solvent), in particular, if a coating solution containing a polymer latex having an equilibrated moisture content of 2 weight % or less at 25°C and relative humidity of 60% is used, the performance is improved. In the most preferred embodiment, the polymer latex is prepared to have an ion conductivity of 2.5 mS/cm or less. An example of a method for preparing such polymer latex includes a method comprising synthesizing a polymer and then purifying the polymer by using a functional membrane for separation.

**[0106]**

The aqueous solvent in which the polymer binder is soluble or dispersible is water or water mixed with 70 weight % or less of a water-miscible organic solvent. Examples of the water-miscible organic solvent include, for example, alcohols such as methyl alcohol, ethyl alcohol and propyl alcohol; cellosolves such as methyl cellosolve, ethyl cellosolve and butyl cellosolve; ethyl acetate, dimethylformamide and so forth.

**[0107]**

The term "aqueous solvent" used herein also encompasses systems in which a polymer is not thermodynamically dissolved but is present in a so-called dispersed state.

**[0108]**

The definition "equilibrated moisture content at 25°C and relative humidity of 60%" used herein can be represented by the following equation, in which  $W^1$  indicates the weight of a polymer at humidity-conditioned equilibrium in an atmosphere of 25°C and relative humidity of 60%, and  $W^0$  indicates the absolute dry weight of the polymer at 25°C. Equilibrated moisture content at 25°C and relative humidity of 60% =  $[(W^1 - W^0)/W^0] \times 100$  (weight %)

**[0109]**

As for details of the definition of moisture content and methods for measurement, for example, Lecture of Polymer Engineering, 14, Test Methods for Polymer Materials (Polymer

Society of Japan, Chijin Shokan) can be referred to.

**[0110]**

The equilibrated moisture content at 25°C and relative humidity of 60% of the binder polymer is preferably 2 weight % or less, more preferably from 0.01–1.5 weight %, most preferably from 0.02–1 weight %.

**[0111]**

In the present invention, polymers dispersible in aqueous solvents are particularly preferred. Examples of systems in the dispersed state include, for example, polymer latex in which fine solid particles of polymer are dispersed, and a system in which a polymer is dispersed in a molecular state or as micelles, both of which are preferred. Dispersed particles preferably have a mean particle size of around 1–50000 nm, more preferably around 5–1000 nm. Particle size distribution of the dispersed particles is not particularly limited, and either those having a broad particle size distribution or those having monodispersed particle size distribution may be used.

**[0112]**

In preferred embodiments of the polymer dispersible in an aqueous solvent, hydrophobic polymers such as acrylic polymers, polyesters, rubbers (e.g., SBR resins), polyurethanes, polyvinyl chlorides, polyvinyl acetates, polyvinylidene chlorides, and polyolefins can preferably be used. The polymers may be linear, branched or crosslinked. They may be so-called homopolymers in which a single kind of monomer is polymerized, or copolymers in which two or more different kinds of monomers are polymerized. The copolymers may be random copolymers or block copolymers. The polymers may have a number average molecular weight of 5,000 to 1,000,000, preferably from 10,000 to 200,000. Polymers having a too small molecular weight fail to give sufficient mechanical strength of the image-forming layer (emulsion layer), and those having a too large molecular weight yield bad film forming property, and both of which are not preferred.

**[0113]**

Specific examples of the preferred polymer latex are mentioned below. They are expressed with the constituent monomers. The numerals parenthesized indicate the contents in terms of weight %. The molecular weights are number average molecular weights.

**[0114]**

P-1: Latex of –MMA(70)–EA(27)–MAA(3)–  
(molecular weight: 37000)

P-2: Latex of –MMA(70)–2EHA(20)–St(5)–AA(5)–  
(molecular weight: 40000)

P-3: Latex of –St(50)–Bu(47)–MMA(3)–  
(molecular weight: 45000)

P-4: Latex of –St(68)–Bu(29)–AA(3)–  
(molecular weight: 60000)

P-5: Latex of –St(71)–Bu(26)–AA(3)–  
(molecular weight: 60000)

P-6: Latex of –St(70)–Bu(27)–IA(3)–  
(molecular weight: 120000)

P-7: Latex of –St(75)–Bu(24)–AA(1)–  
(molecular weight: 108000)

P-8: Latex of –St(60)–Bu(35)–DVB(3)–MAA(2)–  
(molecular weight: 150000)

P-9: Latex of -St(70)-Bu(25)-DVB(2)-AA(3)-  
(molecular weight: 280000)  
P-10: Latex of -VC(50)-MMA(20)-EA(20)-AN(5)-AA(5)-  
(molecular weight: 80000)  
P-11: Latex of -VDC(85)-MMA(5)-EA(5)-MAA(5)-  
(molecular weight: 67000)  
P-12: Latex of -Et(90)-MAA(10)-  
(molecular weight: 12000)  
P-13: Latex of -St(70)-2EHA(27)-AA(3)-  
(molecular weight: 130000)  
P-14: Latex of -MMA(63)-EA(35)-AA(2)-  
(molecular weight: 33000)

**[0115]**

Abbreviations used for the constituent monomers are as follows:

MMA: methyl methacrylate  
EA: ethyl acrylate  
MAA: methacrylic acid  
2EHA: 2-ethylhexyl acrylate  
St: styrene  
Bu: butadiene  
AA: acrylic acid  
DVB: divinylbenzene  
VC: vinyl chloride  
AN: acrylonitrile  
VDC: vinylidene chloride  
Et: ethylene  
IA: itaconic acid

**[0116]**

The polymer latexes mentioned above are also commercially available, and those mentioned below can be used, for example. Examples of acrylic resins are CEBIAN A-4635, 46583, 4601 (all from Daicel Chemical Industries), Nipol Lx811, 814, 821, 820, 857 (all from Nippon Zeon) etc.; examples of polyester resins are FINETEX ES650, 611, 675, 850 (all from Dai-Nippon Ink & Chemicals), WD-size, WMS (both from Eastman Chemical) etc.; examples of polyurethane resins are HYDRAN AP10, 20, 30, 40 (all from Dai-Nippon Ink & Chemicals) etc.; examples of rubber resins are LACSTAR 7310K, 3307B, 4700H, 7132C (all from Dai-Nippon Ink & Chemicals), Nipol Lx416, 410, 438C, 2507 (all from Nippon Zeon) etc.; examples of polyvinyl chloride resins are G351, G576 (both from Nippon Zeon) etc.; examples of polyvinylidene chloride resins are L502, L513 (both from Asahi Chemical Industry) etc.; examples of polyolefin resins are CHEMIPPEARL S120, SA100 (both from Mitsui Petrochemical) etc.

These polymer latexes may be used each alone, or two or more kinds of them may be blended as required.

**[0117]**

As the polymer latex used in the present invention, styrene/butadiene copolymer latex is particularly preferred. In the styrene/butadiene copolymer, the weight ratio of styrene monomer units and butadiene monomer units is preferably 40:60 to 95:5. The ratio of the styrene monomer units and the butadiene monomer units preferably account for from 60-99 weight % of

the copolymer. The preferred range of the molecular weight of the copolymer is similar to that mentioned above.

**[0118]**

Examples of styrene/butadiene copolymer 'latexes' preferably used for the present invention include the aforementioned P-3 to P-8, commercially available products, LACSTAR-3307B, 7132C, Nipol Lx416 and so forth.

**[0119]**

The latex used for the present invention preferably has a glass transition temperature ( $T_g$ ) within the range of 10–80°C, more preferably in the range of 20–60°C. When a blend of two or more kinds of polymers having different glass transition temperatures is used, it is preferred that its weight average  $T_g$  should fall within the aforementioned range.

**[0120]**

The layer containing silver salt of an organic acid of the thermally processed image recording material may optionally contain a hydrophilic polymer such as gelatin, polyvinyl alcohol, methyl cellulose, hydroxypropyl cellulose and carboxymethyl cellulose. The addition amount of the hydrophilic polymer is preferably 30 weight % or less, more preferably 20 weight % or less, of the total binder in the layer containing silver salt of an organic acid.

**[0121]**

The layer containing silver salt of an organic acid (i.e., image-forming layer) is preferably formed by using polymer latex. The amount of the binder in the layer containing silver salt of an organic acid is such an amount that the weight ratio of total binder/silver salt of an organic acid should be 1/10 to 10/1, more preferably 1/5 to 4/1.

**[0122]**

The layer containing silver salt of an organic acid usually also serves as an image-forming layer (photosensitive layer, emulsion layer) containing a photosensitive silver salt, that is, a photosensitive silver halide. In such a case, the weight ratio of total binder/silver halide is preferably 5–400, more preferably 10–200.

**[0123]**

The total amount of the binder in the image-forming layer is preferably 0.2–30 g/m<sup>2</sup>, more preferably 1–15 g/m<sup>2</sup>. The image-forming layer may optionally contain a crosslinking agent for crosslinking, a surfactant for improving coating property and so forth.

**[0124]**

The solvent for the coating solution for the layer containing silver salt of an organic acid of the thermally processed image recording material of the invention (for simplicity, solvents and dispersion media are collectively referred to as solvent) is an aqueous solvent containing at least 30 weight % of water. As for components other than water, any water-miscible organic solvents including, for example, methyl alcohol, ethyl alcohol, isopropyl alcohol, methyl cellosolve, ethyl cellosolve, dimethylformamide, ethyl acetate and so forth may be used. The water content of the solvent for the coating solution is preferably at least 50 weight %, more preferably at least 70 weight %. Preferred examples of the solvent composition are water, water/methyl alcohol = 90/10, water/methyl alcohol = 70/30, water/methyl alcohol/dimethylformamide = 80/15/5, water/methyl alcohol/ethyl cellosolve = 80/10/5, water/methyl alcohol/isopropyl alcohol = 85/10/5 and so forth (numerals indicate weight %).

**[0125]**

As antifoggants, stabilizers and stabilizer precursors that can be used for the present invention, there can be mentioned, for example, those mentioned in JP-A-10-62899, paragraph

0070 and EP0803764A1, from page 20, line 57 to page 21, line 7. Antifoggants preferably used for the present invention are organic halides. Examples thereof include, for example, those disclosed in JP-A-11-65021, paragraphs 0111 to 0112. Particularly preferred are the polyhalogenated compounds represented by the formula (P) mentioned in Japanese Patent Application No. 11-87297, the polyhalogenated compounds represented by the formula (II) mentioned in JP-A-10-339934, the polyhalogenated compounds described in Japanese Patent Application Nos. 11-90095, 11-89561, 11-205329 and 11-205330.

**[0126]**

As the method for introducing an antifoggant into the thermally processed image recording material, the aforementioned method for introducing the reducing agent can be mentioned. The organic polyhalogenated compound is also preferably added in the form of a solid microparticle dispersion.

**[0127]**

Other examples of the antifoggant include the mercury(II) salts described in JP-A-11-65021, paragraph 0113, the benzoic acids described in the same, paragraph 0114, the salicylic acid derivatives represented by the formula (Z) mentioned in Japanese Patent Application No. 11-87297, the formalin scavenger compounds represented by the formula (S) mentioned in Japanese Patent Application No. 11-23995, triazine compounds mentioned in JP-A-11-352624, Claim 9, compounds represented by the formula (III) mentioned in JP-A-6-11791, 4-hydroxy-6-methyl-1,3,3a,7-tetrazaindene and so forth.

**[0128]**

The thermally processed image recording material may contain an azolium salt for prevention of fog. Examples of the azolium salt include, for example, the compounds of the formula (XI) disclosed in JP-A-59-193447, the compounds disclosed in JP-B-55-12581 and the compounds of the formula (II) disclosed in JP-A-60-153039. While the azolium salt may be added in any site of the thermally processed image recording material, it is preferably added in a layer on the side of an image-forming layer, more preferably in the layer containing silver salt of an organic acid. The azolium salt may be added at any time during the preparation of the coating solution. When the azolium salt is added to the layer containing silver salt of an organic acid, the azolium salt may be added at any time during the period of from the preparation of the silver salt of an organic acid to the preparation of the coating solution. A time during the period after the preparation of the silver salt of an organic acid and immediately before coating is preferred. The azolium salt may be added as any form such as powder, solution and microparticle dispersion. The salt may also be added as a solution prepared by mixing the salt with other additives such as a sensitizing dye, reducing agent and toning agent. The amount of the azolium salt to be added is not particularly limited, and the amount may preferably be  $1 \times 10^{-6}$  mole to 2 moles, more preferably  $1 \times 10^{-3}$  mole to 0.5 mole, per mole of silver.

**[0129]**

The thermally processed image recording material may optionally contain a mercapto compound, disulfide compound or thione compound to accelerate, suppress, or control development, or increase efficiency in spectral sensitivity, or to improve storability before and after development. Examples thereof include, for example, those compounds described in JP-A-10-62899, paragraphs 0067 to 0069, compounds of the formula (I) and specific examples thereof mentioned in JP-A-10-186572, paragraphs 0033 to 0052, those described in EP0803764A1, page 20, lines 36 to 56, those described in Japanese Patent Application No. 11-273670. Among them, mercapto-substituted heteroaromatic compounds are preferred.

**【0130】**

A toning agent is preferably added to the thermally processed image recording material. Examples of the toning agent are described in JP-A-10-62899, paragraphs 0054 to 0055, EP0803764A1, page 21, lines 23 to 48 and Japanese Patent Application No. 11-213487. Preferred examples include phthalazinones (e.g., phthalazinone, phthalazinone derivatives such as 4-(1-naphthyl)phthalazinone, 6-chlorophthalazinone, 5,7-dimethoxyphthalazinone and 2,3-dihydro-1,4-phthalazinone metal salts thereof); combinations of phthalazinones and phthalic acids (e.g., phthalic acid, 4-methylphthalic acid, 4-nitrophthalic acid, tetrachlorophthalic anhydride and so forth); phthalazines (e.g., phthalazine, phthalazine derivatives such as 4-(1-naphthyl)phthalazine, 6-isopropyl-phthalazine, 6-t-butylphthalazine, 6-chlorophthalazine, 5,7-dimethoxyphthalazine and 2,3-dihydrophthalazine and metal salts thereof); combinations of phthalazines and phthalic acids. Particularly preferred examples include the combinations of phthalazines and phthalic acids.

**【0131】**

Plasticizers and lubricants that can be used for the image-forming layer are described in JP-A-11-65021, paragraph 0117. Ultrahigh contrast agents for forming ultrahigh contrast images and addition methods and amounts therefor are described in the same publication, paragraph 0118, JP-A-11-223898, paragraphs 0136 to 0193, Japanese Patent Application No. 11-87297, compounds of the formula (H), formulas (1) to (3), formulas (A) and (B) and those mentioned in Japanese Patent Application No. 11-91652 as compounds of the formulas (III) to (V) (specific compounds: Chem. 21 to Chem 24); and hardness enhancement promoters are described in JP-A-11-65021, paragraph 0102, and JP-A-11-223898, paragraphs 0194 to 0195.

**【0132】**

When formic acid or a formic acid salt is used as a strongly fogging substance, it is preferably used on the side having the image-forming layer containing a photosensitive silver halide in an amount of 5 mmol or less, more preferably 1 mmol or less, per 1 mole of silver.

**【0133】**

When an ultrahigh contrast agent is used in the thermally processed image recording material, an acid formed by hydration of diphosphorus pentoxide or a salt thereof is preferably used together with the ultrahigh contrast agent. Examples of the acid formed by hydration of diphosphorus pentoxide or a salt thereof include metaphosphoric acid (salt), pyrophosphoric acid (salt), orthophosphoric acid (salt), triphosphoric acid (salt), tetraphosphoric acid (salt), hexametaphosphoric acid (salt) and so forth. Particularly preferably used acids formed by hydration of diphosphorus pentoxide or salts thereof are orthophosphoric acid (salt) and hexametaphosphoric acid (salt). Specific examples of the salt are sodium orthophosphate, sodium dihydrogenorthophosphate, sodium hexametaphosphate, ammonium hexametaphosphate and so forth. The acid formed by hydration of diphosphorus pentoxide or a salt thereof may be used in a desired amount (Coating amount per 1 m<sup>2</sup> of the thermally processed image recording material) depending on the desired performance including sensitivity and fog. However, it can be used in an amount of preferably 0.1-500 mg/m<sup>2</sup>, more preferably 0.5-100 mg/m<sup>2</sup>.

**【0134】**

The thermally processed image recording material may be provided with a surface protective layer, for example, to prevent adhesion of the image-forming layer. The surface protective layer may consist of a single layer or a plurality of layers. The surface protective layer is described in, for example, JP-A-11-65021, paragraphs 0119 to 0120.

While gelatin is preferred as the binder in the surface protective layer, polyvinyl alcohol

(PVA) is also preferably used. As the gelatin, for example, inert gelatin (e.g., Nitta Gelatin 750), phthalized gelatin (e.g., Nitta Gelatin 801) and so forth can be used. Examples of PVA include, for example, completely saponified PVA, PVA-105, partially saponified PVA, PVA-205 and PVA-335, modified polyvinyl alcohol, MP-203 (all from Kuraray Co., Ltd.) and so forth. The application amount of the polyvinyl alcohol (per  $\text{m}^2$  of the support) for protective layers is preferably 0.3–4.0  $\text{g}/\text{m}^2$ , more preferably 0.3–2.0  $\text{g}/\text{m}^2$  (per one layer).

**[0135]**

When the thermally processed image recording material is used for, in particular, printing use in which dimensional change is critical, polymer latex is preferably used also in a protective layer or a back layer. Such latex is described in "Gosei Jushi Emulsion (Synthetic Resin Emulsion)", compiled by Taira Okuda and Hiroshi Inagaki, issued by Kobunshi Kanko Kai (1978); "Gosei Latex no Oyo (Application of Synthetic Latex)", compiled by Takaaki Sugimura, Yasuo Kataoka, Souichi Suzuki and Keishi Kasahara, issued by Kobunshi Kanko Kai (1993); Soichi Muroi, "Gosei Latex no Kagaku Chemistry of Synthetic Latex", Kobunshi Kanko Kai (1970) and so forth. Specific example thereof include latex of methyl methacrylate (33.5 weight %)/ethyl acrylate (50 weight %)/methacrylic acid (16.5 weight %) copolymer, latex of methyl methacrylate (47.5 weight %)/butadiene (47.5 weight %)/itaconic acid (5 weight %) copolymer, latex of ethyl acrylate/methacrylic acid copolymer, latex of methyl methacrylate (58.9 weight %)/2-ethylhexyl acrylate (25.4 weight %)/ethylene (8.6 weight %)/2-hydroxyethyl methacrylate (5.1 weight %)/acrylic acid (2.0 weight %) copolymer, latex of methyl methacrylate (64.0 weight %)/styrene (9.0 weight %)/butyl acrylate (20.0 weight %)/2-hydroxyethyl methacrylate (5.0 weight %)/acrylic acid (2.0 weight %) copolymer and so forth. As for the binder of the protective layer, there may be used the combination of polymer latex disclosed in Japanese Patent Application No. 11-6872, and techniques disclosed in Japanese Patent Application No. 11-143058, paragraphs 0021-0025, Japanese Patent Application No. 11-6872, paragraphs 0027-0028, and Japanese Patent Application No. 11-199626, paragraphs 0023-0041. The ratio of the polymer latex in the surface protective layer with respect to the total binder is preferably 10–90 weight%, particularly preferably 20–80 weight %.

Coated amount of the total binder (including wafer-soluble polymer and latex polymer) in the surface protective layer (for one layer) is preferably 0.3–5.0  $\text{g}/\text{m}^2$ , more preferably 0.3–2.0  $\text{g}/\text{m}^2$  (per  $\text{m}^2$  of the support).

**[0136]**

The temperature for preparation of the coating solution for the image-forming layer may preferably be 30°C to 65°C, more preferably 35°C to 60°C, most preferably 35°C to 55°C. The temperature of the coating solution immediately after the addition of the polymer latex may preferably be kept at 30°C to 65°C. A reducing agent and a silver salt of an organic acid may preferably be mixed before the addition of polymer latex.

**[0137]**

The image-forming layer is provided as one or more layers on the support. When it is provided as a monolayer, the layer must contain a silver salt of an organic acid, photosensitive silver halide, reducing agent and binder, and it may contain desired additional materials such as toning agent, coating aid and other auxiliary agents. When the layer is bilayer, the first image-forming layer (in general, the layer adjacent to the support) must contain a silver salt of an organic acid and silver halide, and the second image-forming layer or said two layers must contain the other ingredients. Multicolor photothermographic material may contain these two layers for each color, or may contain all necessary ingredients in a single layer as described in U.S. Patent

No. 4,708,928. As for multicolor photothermographic materials containing multiple dyes, each image-forming layer (emulsion layer) is kept individually by using a functional or non-functional barrier layer between the adjacent photosensitive layers as described in U.S. Patent No. 4,460,681.

**[0138]**

In the image-forming layer, various types of dyes and pigments may be used to improve color tone, to prevent interference fringes generated during laser exposure, and to prevent irradiation (e.g., C.I. Pigment Blue 60, C.I. Pigment Blue 64, C.I. Pigment Blue 15:6). These techniques are detailed in International Patent Publication WO98/36322, JP-A-10-268465, JP-A-11-338098 and so forth.

**[0139]**

In the thermally processed image recording material, an antihalation layer may be provided in a distant position from a light source relative to the image-forming layer.

**[0140]**

Thermally processed image recording materials generally have non-photosensitive layers in addition to the image-forming layer (photosensitive layer). Depending on their positions, the non-photosensitive layers are classified into (1) a protective layer to be provided on an image-forming layer (the opposite side of the support); (2) an intermediate layer to be provided between two or more of image-forming layers or between an image-forming layer and a protective layer; (3) an undercoat layer to be provided between an image-forming layer and a support; (4) a back layer to be provided on a side opposite to the image-forming layer. The filter layer is provided in the thermally processed image recording material as the layer (1) or (2). The antihalation layer is provided in the thermally processed image recording material as the layer (3) or (4).

**[0141]**

The antihalation layer is described in JP-A-11-65021, paragraphs 0123 to 0124, JP-A-11-223898, JP-A-9-230531, JP-A-10-36695, JP-A-10-104779, JP-A-11-231457, JP-A-11-352625, JP-A-11-352626 etc.

The antihalation layer contains an antihalation dye that shows absorption for the light exposure wavelength. When the light exposure wavelength is in the infrared region, an infrared absorption dye can be used, and in such a case, it is preferable to use a dye that does not show absorption for the visible region.

When the antihalation is attained by using a dye that shows absorption for the visible region, it is preferably used in such a manner that color of the dye should not substantially remain after the image formation. To this end, means for enabling decoloration by the heat of heat development is preferably used, and it is particularly preferable to add a thermodecoloring dye and a base precursor to a non-photosensitive layer so that the layer should function as an antihalation layer. These techniques are disclosed in JP-A-11-231457 and so forth.

**[0142]**

The amount of the decoloring dye may be determined depending on purpose of the dye. In general, the dye is used in an amount to give an optical density (absorbance) of larger than 0.1 measured at an intended wavelength. The optical density is preferably 0.2 to 2. The amount of the dye to give such optical density may be generally from about 0.001 to about 1 g/m<sup>2</sup>.

**[0143]**

Decoloring of dyes in that manner can lower optical density of the material to 0.1 or less. Two or more different decoloring dyes may be used in the thermodecoloring type recording

materials or thermally processed image recording materials. Similarly, two or more different base precursors may be used in combination.

In such thermal decoloration utilizing a decoloring dye and base precursor, it is preferable to use together a substance that decreases the melting point by 3°C (deg) or more when it is mixed with a base precursor, such as those described in JP-A-11-352626 (e.g., diphenylsulfone, 4-chlorophenyl-(phenyl)sulfone) in view of thermodecoloration property etc.

**[0144]**

A colorant that shows absorption maximum in the range of 300–450 nm may be added in order to improve change of silver color tone and images with time. Such a colorant is described in JP-A-62-210458, JP-A-63-104046, JP-A-63-103235, JP-A-63-208846, JP-A-63-306436, JP-A-63-314535, JP-A-01-61745, Japanese Patent Application No. 11-276751 and so forth.

Such a colorant is usually added in an amount of 0.1 mg/m<sup>2</sup> to 1 g/m<sup>2</sup>, and it is preferably added to a back layer, which is provided on the side opposite to the side on which the image-forming layer is provided.

**[0145]**

The thermally processed image recording material is preferably a so-called single-sided photosensitive material comprising at least one image-forming layer containing a silver halide emulsion on one side of support, and a back layer on the other side.

**[0146]**

The thermally processed image recording material may preferably contain a matting agent for improving the transferability of the material. Matting agents are described in JP-A-11-65021, paragraphs 0126 to 0127. The matting agent is preferably added in an amount of 1–400 mg/m<sup>2</sup>, more preferably 5 to 300 mg/m<sup>2</sup>, as the amount per 1 m<sup>2</sup> of the thermally processed image recording material.

While the matting degree of the surface of the emulsion layer is not particularly limited so long as the material is free from stardust defects, Beck's smoothness of the surface is preferably 30 seconds to 2000 seconds, more preferably 40 seconds to 1500 seconds. Beck smoothness can be easily determined according to Japanese Industrial Standard (JIS) P8119, "Test Method for Smoothness of Paper and Paperboard by Beck Test Device" and TAPPI Standard Method T479.

**[0147]**

The matting degree of the back layer is preferably falls 10 seconds to 1200 seconds, more preferably 20 seconds to 800 seconds, further preferably 40 seconds to 500 seconds in terms of the Beck's smoothness.

**[0148]**

The matting agent may preferably be incorporated in the outermost surface layer or a layer which functions as the outermost surface layer of the thermally processed image recording material, or alternatively, in a layer close to the outer surface or a layer which acts as a so-called protective layer.

**[0149]**

The back layers that are applicable to the thermally processed image recording material are described in JP-A-11-65021, paragraphs 0128 to 0130.

**[0150]**

The thermally processed image recording material preferably has a film surface pH of 6.0 or less, more preferably 5.5 or less before heat development. While the lower limit is not particularly defined, it is normally around 3. For controlling the film surface pH, an organic acid

such as phthalic acid derivatives or a nonvolatile acid such as sulfuric acid, and a volatile base such as ammonia are preferably used to lower the film surface pH. In particular, ammonia is preferred to achieve a low film surface pH, because it is highly volatile and therefore it can be removed before coating or heat development. A method for measuring the film surface pH is described in Japanese Patent Application No. 11-87297, paragraph 0123.

**[0151]**

A hardening agent may be added to the image-forming layer, the protective layer, the back layer and other layers. Examples of the hardening agent are described in T.H. James, "THE THEORY OF THE PHOTOGRAPHIC PROCESS, FOURTH EDITION", Macmillan Publishing Co., Inc., 1977, pp. 77-87. There may be preferably used chromium alum, 2,4-dichloro-6-hydroxy-s-triazine sodium salt, N,N-ethylenebis(vinylsulfonacetamide), N,N-propylene-bis(vinylsulfonacetamide), as well as the polyvalent metal ions described on page 78 of the above article, polyisocyanates described in U.S. Patent No. 4,281,060 and JP-A-6-208193; epoxy compounds described in U.S. Patent No. 4,791,042; vinylsulfone compounds described in JP-A-62-89048 and so forth.

**[0152]**

The hardening agent is added to coating solutions as a solution. Preferred addition time of the solution to the coating solution of the protective layer resides in a period of from 180 minutes before the coating to just before the coating, preferably 60 minutes to 10 seconds before the coating. The method and conditions for mixing are not particularly limited. Specific examples of the mixing method include a method in which a mixing is performed in a tank designed so as to obtain a desired average residence time which is calculated from addition flow rate and feeding amount to a coater, a method utilizing a static mixer described in N. Harnby, M.F. Edwards, A.W. Nienow, "Ekitai Kongo Gijutsu (Techniques for Mixing Liquids)", translated by Koji Takahashi, Chapter 8, Nikkan Kogyo Shinbunsha, 1989 and so forth.

**[0153]**

Surfactants that can be used in the present invention are described in JP-A-11-65021, paragraph 0132; usable solvents are described in the above patent document in paragraph 0133; usable supports are described in the above patent document in paragraph 0134; usable antistatic and electroconductive layers are described in the above patent document in paragraph 0135; and usable methods for forming color images are described in the above patent document in paragraph 0136; lubricants are described in JP-A-11-84573, paragraphs 0061-0064 and Japanese Patent Application No. 11-106881, paragraphs 0049-0062.

**[0154]**

Preferably used as a transparent support is a polyester film, in particular, polyethylene terephthalate film, subjected to a heat treatment in a temperature range of 130-185°C in order to relax the internal distortion formed in the film during the biaxial stretching so that thermal shrinkage distortion occurring during the heat development should be eliminated. When the thermally processed image recording material is for medical use, the transparent support may be colored with blue dyes (e.g., with Dye-1 described in Examples of JP-A-8-240877), or may be colorless. For the support, techniques for undercoating described in JP-A-11-84574 (utilizing water-soluble polyester), JP-A-10-186565 (utilizing styrene/butadiene copolymer), JP-A-11-106881, paragraphs 0063-0080 (utilizing vinylidene chloride copolymer) and so forth are preferably used. As for antistatic layers and undercoating, techniques disclosed in JP-A-56-143430, JP-A-56-143431, JP-A-58-62646, JP-A-56-120519, JP-A-11-84573, paragraphs 0040-0051, U.S. Patent No. 5,575,957, JP-A-11-223898, paragraphs 0078-0084 and

so forth can also be used.

**[0155]**

The thermally processed image recording material is preferably a monosheet type material (the monosheet uses no additional sheet as required by image receiving materials, and can form images directly on the thermally processed image recording material itself).

**[0156]**

The thermally processed image recording material may further contain an antioxidant, a stabilizer, a plasticizer, an ultraviolet absorber or a coating aid. Such additives may be added to any of image-forming layers (photosensitive layers) or non-photosensitive layers. For these additives, WO98/36322, EP803764A1, JP-A-10-186567, JP-A-10-18568 and so forth may be referred to.

**[0157]**

The coating method for the preparation of the thermally processed image recording material of the present invention is not particularly limited, and any coating methods may be employed. Specific examples thereof include various types of coating techniques, for example, extrusion coating, slide coating, curtain coating, dip coating, knife coating, flow coating, extrusion coating utilizing a hopper of the type described in U.S. Patent No. 2,681,294 and so forth. Preferred examples include extrusion coating and slide coating described in Stephen F. Kistler, Petert M. Schweizer, "LIQUID FILM COATING", published by CHAPMAN & HALL Co., Ltd., 1997, pp.399-536, and a most preferable example includes the slide coating. An example of the shape of a slide coater used for the slide coating is shown in Figure 11b, 1, on page 427 of the aforementioned reference. If desired, two or more layers may be formed at the same time, for example, according to the methods described from page 399 to page 536 of the aforementioned reference, or the methods described in U.S. Patent No. 2,761,791 and British Patent No. 837,095.

**[0158]**

The coating solution for the image-forming layer is preferably a so-called thixotropic flow. Thixotropy means a property of fluid that viscosity of fluid lowers with increase of shear rate. While any apparatus may be used for measurement of viscosity, for example, RFS Fluid Spectrometer from Rheometrics Far East Co., Ltd. is preferably used and the measurement is performed at 25°C. Viscosity of the coating solution for the image-forming layer is preferably 400 mPa·s to 100,000 mPa·s, more preferably 500 mPa·s to 20,000 mPa·s, at a shear rate of 0.1 sec<sup>-1</sup>. The viscosity is preferably 1 mPa·s to 200 mPa·s, more preferably 5 mPa·s to 80 mPa·s, at a shear rate of 1000 sec<sup>-1</sup>.

**[0159]**

Various systems exhibiting thixotropic property are known and, for example, described in "Koza Rheology (Lecture on Rheology)", Kobunshi Kanko Kai; Muroi & Morino, "Kobunshi Latex (Polymer Latex)", Kobunshi Knako Kai and so forth. A fluid is required to contain a large amount of fine solid microparticles to exhibit thixotropic property. For enhancing thixotropic property, it is effective that the fluids is added with a viscosity-increasing linear polymer, or fine solid microparticles to be contained have anisotropic shapes and an increased aspect ratio. Use of an alkaline viscosity-increasing agent or a surfactant is also effective for that purpose.

**[0160]**

Other techniques that can be used for the production of the thermally processed image recording material are also described in EP803764A1, EP883022A1, WO98/36322, JP-A-56-62648, JP-A-58-62744, JP-A-9-281637, JP-A-9-297367, JP-A-9-304869, JP-A-9-311405, JP-A-9-329865, JP-A-10-10669, JP-A-10-62899, JP-A-10-69023,

JP-A-10-186568, JP-A-10-90823, JP-A-10-171063, JP-A-10-186565, JP-A-10-186567, JP-A-10-186569, JP-A-10-186570, JP-A-10-186571, JP-A-10-186572, JP-A-10-197974, JP-A-10-197982, JP-A-10-197983, JP-A-10-197985, JP-A-10-197986, JP-A-10-197987, JP-A-10-207001, JP-A-10-207004, JP-A-10-221807, JP-A-10-282601, JP-A-10-288823, JP-A-10-288824, JP-A-10-307365, JP-A-10-312038, JP-A-10-339934, JP-A-11-7100, JP-A-11-15105, JP-A-11-24200, JP-A-11-24201, JP-A-11-30832, JP-A-11-84574, JP-A-11-65021, JP-A-11-109547, JP-A-11-125880, JP-A-11-129629, JP-A-11-133536, JP-A-11-133537, JP-A-11-133538, JP-A-11-133539, JP-A-11-133542, JP-A-11-133543, JP-A-11-223898 and JP-A-11-352627.

**[0161]**

The thermally processed image recording material of the invention may be developed in any manner. Usually, an imagewise exposed thermally processed image recording material is developed by heating. The temperature for the development is preferably 80°C to 250°C, more preferably 100°C to 140°C. The development time is preferably 1-180 seconds, more preferably 10-90 seconds, particularly preferably 10-40 seconds.

**[0162]**

For thermal development for the material, preferred is a plate heater system. For heat development by the plate heater system, the method described in JP-A-11-133572 is preferred. The plate heater system described in this references is a heat development apparatus wherein a thermally processed image recording material on which a latent image is formed is brought into contact with a heating means in a heat development section to obtain a visible image. In this apparatus, the heating means comprises a plate heater, and a plurality of presser rollers are disposed facing to one surface of the plate heater. Heat development of the thermally processed image recording material is attained by passing the material between the presser rollers and the plate heater. The plate heater is preferably sectioned into 2 to 6 stages, and the temperature of the top stage is preferably kept lower by 1 to 10°C or so than that of the others. Such a method is also described in JP-A-54-30032. Such a plate heater system can remove moisture and organic solvent contained in the thermally processed image recording material out of the material, and prevent deformation of the support of the thermally processed image recording material due to rapid heating of the material.

**[0163]**

The thermally processed image recording material of the present invention can be exposed in any manner. As light source of exposure, laser rays are preferred. As the laser used in the present invention, gas lasers (Ar<sup>+</sup>, He-Ne), YAG lasers, dye lasers, semiconductor lasers and so forth are preferred. A combination of semiconductor laser and second harmonic generating device may also be used. Preferred are gas or semiconductor lasers for red to infrared emission.

**[0164]**

As an example of a laser imager provided with a light exposure section and a heat development section, Fuji Medical Dry Laser Imager FM-DP L can be mentioned. FM-DP L is explained in Fuji Medical Review, No. 8, pages 39-55, and those techniques can of course be used in laser imagers for the thermally processed image recording material. Further, it can be used as a thermally processed image recording material for laser imagers in "AD network", which was proposed by Fuji Medical System as a network system that conforms to the DICOM standard.

**[0165]**

The thermally processed image recording material forms a monochromatic image based

on silver image, and is preferably used as a thermally processed image recording material for use in medical diagnosis, industrial photography, printing and COM.

[0166]

[Example]

The present invention will be specifically explained with reference to the following examples. The materials, amounts, ratios, types of treatments, procedures of treatments and so forth shown in the following examples can be optionally changed so long as such change does not depart from the spirit of the present invention. Therefore, the scope of the present invention is not limited to the following examples.

[0167]

<Comparative Example 1>

In an amount of 876 g of behenic acid (Edenor C22-85R, trade name, manufactured by Henkel Co.), 4230 mL of distilled water and 1200 mL of tert-butanol stirred at 75°C in a reaction tank were added with 492 mL of 5 mol/L aqueous solution of NaOH over 5 minutes, and allowed to react for 60 minutes to obtain a solution of sodium behenate. Separately, 2062 mL of an aqueous solution containing 404 g of silver nitrate (pH 4.0) was prepared and kept at 10°C. A reaction vessel containing 6350 mL of distilled water and 300 mL of tert-butanol was maintained at 30°C, and added with the whole volume of the aqueous silver nitrate solution with stirring at a constant flow rate. After 7 minutes, it was started to add the whole volume of the sodium behenate solution at a constant flow rate. The addition times of the aqueous silver nitrate solution and the sodium behenate solution in this operation were 60 minutes and 62 minute, respectively. Therefore, during the last 9 minutes, only the sodium behenate solution was added. The mixture was left as it was with stirring for 20 minutes to lower the temperature to 25°C. The obtained aqueous dispersion of organic acid silver salt showed pH of 6.3.

[0168]

The obtained aqueous dispersion of organic acid silver salt was transferred to the ultrafiltration unit shown in Fig. 1 to subject it to desalting treatment. The ultrafiltration module used was ACP-1050 produced by Asahi Chemical Industry Co., Ltd. (hollow-fiber membrane). As the filtration scheme, cross flow method was used. The feeding flow rate was 12 L/minute, average filtration pressure was 1.5 kgf/cm<sup>2</sup>, and operation temperature was 20°C. While the organic acid silver salt concentration was about 5.4 weight % at the start of the desalting treatment, it increased to 10 weight % as the treatment advanced. When the concentration reached 10 weight %, addition of water for constant volume dilution was started. As a solution for constant volume dilution, an aqueous solution of sodium diisobutyl naphthalenesulfonate (Concentration: 0.3 weight %) was used in such a manner that the concentration of dispersing agent should be constant. During the desalting treatment, pH was continuously monitored and maintained at the predetermined level. When the electric conductivity became less than 300  $\mu$ S/cm, the pH adjustment and supplementation of water were stopped, and concentration operation was started. The concentration operation was performed until the solid content concentration reached 25 weight %. The filtration rate at the endpoint of the concentration was measured. Further, viscosity of Organic acid silver salt dispersion A obtained after the concentration was measured by using a B-type viscometer. The solid content was measured by using a digital specific gravimeter, Model DA-300, produced by Kyoto Electronics Manufacturing Co., Ltd., and finally determined based on absolute dry weight.

[0169]

<Example 1>

<Preparation of Organic acid silver salt grain dispersion B>

• Addition of solutions of sodium behenate and silver nitrate was performed in the same manner as that for Organic acid silver salt aqueous dispersion A. The obtained aqueous dispersion of organic acid silver salt was treated in a dispersing machine (Microfluidizer M-110S-EH; trade name, manufactured by Microfluidex International Corporation, using G10Z interaction chamber) at a pressure controlled to be 600 kg/cm<sup>2</sup>.

Then, the dispersion was transferred to the ultrafiltration unit shown in Fig. 1, and subjected to desalting and concentration treatments in the same manner as in Comparative Example 1 to obtain Organic acid silver salt aqueous dispersion B.

【0170】

<Example 2>

<Preparation of organic acid silver salt grain dispersion C>

Addition of solutions of sodium behenate and silver nitrate was performed in the same manner as that for Organic acid silver salt aqueous dispersion A.

The obtained aqueous dispersion of organic acid silver salt was simultaneously subjected to dispersion and desalting by ultrafiltration in the apparatus shown in Fig. 2. The dispersing machine used was a rotary type dispersing machine (Milder MDN 303V produced by Ebara Corp.), and the treatment was performed at a rotation number of 15,000 rpm with cooling of the outside with cooling water at 10°C. The feeding flow rate was 4 L/minute.

By using exactly the same ultrafiltration module, filtration conditions and conditions for the subsequent concentration as those in Comparative Example 1, Organic acid silver salt aqueous dispersion C was obtained.

【0171】

The preparation conditions of Organic acid silver salt aqueous dispersions A to C and so forth are summarized in Table 1. As seen from the results shown in Table 1 below, it was confirmed that the viscosity at the endpoint of the concentration could be suppressed to a low level and the filtration rate could be maintained at a high level by performing dispersion treatment before or during the concentration by ultrafiltration according to the present invention.

【0172】

【Table 1】

	Dispersing machine	State at end point of concentration		State of silver salt of organic acid	
		Viscosity (Pa·s)	Filtration Rate [L/(m <sup>2</sup> ·h)]	Shape of silver salt of organic acid	Average grain size (μm)
A (Comparative)	—	0.113	5	scaly grain	0.68
B (Invention)	High pressure homogenizer	0.012	20	scaly grain	0.61
C (Invention)	Rotary type dispersing machine	0.011	22	scaly grain	0.62

【0173】

<Example 3>

In present example, a thermally processed image recording material is prepared by using a silver salt of an organic acid produced in Examples 1 and 2.

**[0174]**

**<<Preparation of undercoated PET support>>**

**(Preparation of PET support)**

Using terephthalic acid and ethylene glycol, polyethylene terephthalate having an intrinsic viscosity of 0.66 (measured in phenol/tetrachloroethane = 6/4 (weight ratio) at 25°C) was obtained in a conventional manner. This was pelletized, and the pellets were dried at 130°C for 4 hours, melted at 300°C, extruded from a T-die, and quenched to prepare an unstretched film having such a thickness that the film thickness after thermal fixation should become 175 micrometers.

The film was stretched along the longitudinal direction by 3.3 times at 110°C using rollers having different peripheral speeds and then stretched along the transverse direction at 130°C by 4.5 times using a tenter. Thereafter, the film was subjected to thermal fixation at 240°C for 20 seconds and relaxed by 4% along the transverse direction at the same temperature. Then, after chucks of the tenter were released, the both edges of the film were knurled, and the film was rolled up at 4 kg/cm<sup>2</sup> to provide a roll of the film having a thickness of 175 micrometers.

**[0175]**

**《Surface corona discharging treatment》**

Using a solid state corona discharging treatment machine Model 6KVA manufactured by Piller Inc., both surfaces of the support were treated at room temperature at 20 m/minute. In this case, from the read out values of the electric current and voltage, it was seen that the treatment of 0.375 kV·A·minute/m<sup>2</sup> was applied to the support. The treated frequency in this case was 9.6 kHz and the gap clearance between the electrode and the dielectric roll was 1.6 mm.

**[0176]**

**《Preparation of undercoated support》**

#### **[0179]**

(Preparation of undercoated support)

After applying the aforementioned corona discharging treatment to both surfaces of the aforementioned biaxially stretched polyethylene terephthalate support having a thickness of 175 micrometers, one surface (photosensitive layer side) thereof was coated with the undercoating solution of Formulation 1 by a wire bar in a wet coating amount of 6.6 ml/m<sup>2</sup> (per one surface) and dried at 180°C for 5 minutes. Then, the back surface thereof was coated with the undercoating solution of Formulation 2 by a wire bar in a wet coating amount of 5.7 ml/m<sup>2</sup> and dried at 180°C for 5 minutes. The back surface thus coated was further coated with the undercoating solution of Formulation 3 by a wire bar in a wet coating amount of 7.7 ml/m<sup>2</sup> and dried at 180°C for 6 minutes to prepare an undercoated support.

#### **[0180]**

<<Preparation of coating solution for back surface>>

(Preparation of Solid microparticle dispersion (a) of base precursor)

In an amount of 64 g of Base precursor compound 11, 28 g of diphenylsulfone and 10 g of a surface active agent, Demor N (manufactured by Kao Corporation), were mixed with 220 ml of distilled water, and the mixture was beads-dispersed using a sand mill (1/4 Gallon Sand Grinder Mill, manufactured by Imex Co.) to obtain Solid microparticle dispersion (a) of the base precursor compound having a mean particle size of 0.2 micrometers.

#### **[0181]**

(Preparation of dye solid microparticle dispersion)

In an amount of 9.6 g of Cyanine dye compound 13 and 5.8 g of sodium p-dodecylbenzenesulfonate were mixed with 305 ml of distilled water and the mixture was beads-dispersed using a sand mill (1/4 Gallon Sand Grinder Mill, manufactured by Imex Co.) to obtain a dye solid microparticle dispersion having a mean particle size of 0.2 micrometers.

(Preparation of coating solution for antihalation layer)

In an amount of 17 g of gelatin, 9.6 g of polyacrylamide, 70 g of the aforementioned Solid microparticle dispersion (a) of the base precursor, 56 g of the aforementioned dye solid microparticle dispersion, 1.5 g of monodispersed polymethyl methacrylate microparticles (mean particle size: 8 micrometers, standard deviation of particle size: 0.4), 0.03 g of benzoisothiazolinone, 2.2 g of sodium polyethylenesulfonate, 0.2 g of Blue dye compound 14, 3.9 g of Yellow dye compound 15 and 844 ml of water were mixed to prepare a coating solution for antihalation layer.

**【0183】**

(Preparation of coating solution for back surface protective layer)

In a container kept at 40°C, 50 g of gelatin, 0.2 g of sodium polystyrenesulfonate, 2.4 g of N,N-ethylenebis(vinyl-sulfonacetamide), 1 g of sodium t-octylphenoxyethoxyethane-sulfonate, 30 mg of benzoisothiazolinone, 37 mg of N-perfluoro-octylsulfonyl-N-propylalanine potassium salt, 0.15 g of polyethylene glycol mono(N-perfluorooctylsulfonyl-N-propyl-2-aminoethyl) ether [average polymerization degree of ethylene oxide: 15], 32 mg of  $C_8F_{17}SO_3K$ , 64 mg of  $C_8F_{17}SO_2NC_3H_7CH_2CH_2O)_4CH_2)_4-SO_3Na$ , 8.8 g of an acrylic acid/ethyl acrylate copolymer Copolymerization ratio (weight ratio): 5/95, 0.6 g of Aerosol OT (manufactured by American Cyanamid Company), 1.8 g (as liquid paraffin) of a liquid paraffin emulsion and 950 ml of water were mixed to form a coating solution for back surface protective layer.

**【0184】**

<<Preparation of Silver halide emulsion 1>>

In an amount of 1421 ml of distilled water was added with 3.1 ml of 1 weight % potassium bromide solution, and further added with 3.5 ml of 0.5 mol/L sulfuric acid and 31.7 g of phthalized gelatin. Separately, Solution A was prepared by adding distilled water to 22.22 g of silver nitrate to dilute it to 95.4 ml, and Solution B was prepared by diluting 15.9 g of potassium bromide with distilled water to a volume of 97.4 ml. To the aforementioned mixture maintained at 34°C and stirred in a titanium-coated stainless steel reaction vessel, the whole volume of Solution A and Solution B was added over 45 seconds at constant flow rates. Then, the mixture was added with 10 ml of 3.5 weight % aqueous hydrogen peroxide solution, and further added with 10.8 ml of a 10 weight % aqueous solution of benzimidazole. Further, Solution C was prepared by adding distilled water to 51.86 g of silver nitrate to dilute it to 317.5 ml, and Solution D was prepared by diluting 45.8 g of potassium bromide with distilled water to a volume of 400 ml. The whole volume of Solution C was added to the mixture over 20 minutes at a constant flow rate. Solution D was added by the control double jet method while pAg was maintained at 8.1. Hexachloroiridic acid (III) potassium salt in an amount of  $1 \times 10^{-4}$  mole per mole of silver was added at one time 10 minutes after the addition of Solutions C and D was started. Further, an aqueous solution of potassium iron(II) hexacyanide in an amount of  $3 \times 10^{-4}$  mole per mole of silver was added at one time 5 seconds after the addition of Solution C was completed. Then, the mixture was adjusted to pH 3.8 using 0.5 mol/L sulfuric acid, and the stirring was stopped. Then, the mixture was subjected to precipitation, desalting and washing with water, adjusted to pH 5.9 with 1 mol/L sodium hydroxide to form a silver halide dispersion having pAg of 8.0.

**【0185】**

The aforementioned silver halide dispersion was added with 5 ml of a 0.34 weight % methanol solution of 1,2-benzisothiazolin-3-one with stirring at 38°C, and after 40 minutes since then, added with a methanol solution of Spectral sensitizing dye A in an amount of  $1 \times 10^{-3}$  mole per mole of silver. After 1 minutes, the mixture was warmed to 47°C, and 20 minutes after the warming, added with  $7.6 \times 10^{-5}$  mole of sodium benzenethiosulfonate per mole of silver as a methanol solution. Further after 5 minutes, the mixture was added with Tellurium sensitizer B as a methanol solution in an amount of  $1.9 \times 10^{-4}$  mole per mole of silver followed by ripening for 91 minutes. The mixture was added with 1.3 ml of a 0.8 weight % methanol solution of N,N'-dihydroxy-N"-diethylmelamine, and 4 minutes later, added with  $3.7 \times 10^{-3}$  mole per mole of silver of 5-methyl-2-mercaptobenzimidazole and  $4.9 \times 10^{-3}$  mole per mole of silver of 1-phenyl-2-heptyl-5-mercapto-1,3,4-triazole as a methanol solution to prepare Silver halide emulsion 1.

The grains in the prepared silver halide emulsion were pure silver bromide grains having a mean diameter as spheres of 0.046 micrometers and a variation coefficient of 20% for mean diameter as spheres. The grain size and others were obtained from averages for 1000 grains by using an electron microscope. The [100] face ratio of these grains was determined to be 80% by the Kubelka-Munk method.

**[0186]**

<<Preparation of Silver halide emulsion 2>>

Silver halide emulsion 2 was prepared in the same manner as the preparation of Silver halide emulsion 1 except that the liquid temperature upon grain formation was changed from 34°C to 49°C, addition time of Solution C was changed to 30 minutes and potassium iron(II) hexacyanide was not used. Then, as in the case of Silver halide emulsion 1, the steps of precipitation, desalting, washing with water and dispersion were performed. Furthermore, in the same manner as in the case of Silver halide emulsion 1 except that the addition amount of Spectral sensitizing dye A was changed to  $7.5 \times 10^{-4}$  mole per mole of silver, the addition amount of Tellurium sensitizer B was changed to  $1.1 \times 10^{-4}$  mole per mole of silver, and the addition amount of 1-phenyl-2-heptyl-5-mercapto-1,3,4-triazole was changed to  $3.3 \times 10^{-3}$  mole of per mole of silver, spectral sensitization, chemical sensitization, and addition of 5-methyl-2-mercaptobenzimidazole and 1-phenyl-2-heptyl-5-mercapto-1,3,4-triazole were performed to obtain Silver halide emulsion 2. Emulsion grains of Silver halide emulsion 2 were pure silver bromide cubic grains having a mean grain diameter of 0.080 micrometers as spheres and a variation coefficient of 20% for diameter as spheres.

**[0187]**

<<Preparation of Silver halide emulsion 3>>

Silver halide emulsion 3 was prepared in the same manner as the preparation of Silver halide emulsion 1 except that the liquid temperature upon grain formation was changed from 34°C to 27°C. Further, as in the case of Silver halide emulsion 1, the steps of precipitation, desalting, washing with water and dispersion were performed. Then, Silver halide emulsion 3 was obtained in the same manner as in the case of Silver halide emulsion 1 except that the addition amount of Spectral sensitizing dye A solid dispersion (gelatin aqueous solution) was changed to  $6 \times 10^{-3}$  mole per mole of silver and the addition amount of Tellurium sensitizer B was changed to  $5.2 \times 10^{-4}$  mole per mole of silver. Emulsion grains of Silver halide emulsion 3 were pure silver bromide cubic grains having a mean grain diameter of 0.038 micrometers as spheres and a variation coefficient of 20% for diameter as spheres.

**[0188]**

<<Preparation of Mixed emulsion A for coating solution>>

In an amount of 70% by weight of Silver halide emulsion 1, 15% by weight of Silver halide emulsion 2 and 15% by weight of Silver halide emulsion 3 were mixed and added with benzothiazolium iodide in an amount of  $7 \times 10^{-3}$  mole per mole of silver as a 1 weight % aqueous solution.

**[0189]**

<<Preparation of 25 weight % dispersion of reducing agent complex>>

In an amount of 10 kg of 1,1-bis-(2-hydroxy-3,5-dimethyl-phenyl)-3,5,5-trimethylhexane and 20 weight % aqueous solution of modified polyvinyl alcohol (Poval MP203, manufactured by Kuraray Co., Ltd.) was added 16 kg of water, and the mixture was mixed sufficiently to form slurry. The slurry was fed by a diaphragm pump to a sand mill of horizontal type (UVM-2, manufactured by Imex Co.) containing zirconia beads having a mean diameter of 0.5 mm, and

dispersed for 3 hours and 30 minutes. Then, the slurry was added with 0.2 g of benzothiazolinone sodium salt and water so that the concentration of the reducing agent should become 25 weight % to obtain a solid microparticle dispersion of reducing agent complex. The reducing agent complex particles contained in the dispersion of reducing agent complex obtained above had a median diameter of 0.46 micrometers and the maximum particle size of 2.0 micrometers or less. The obtained reducing agent complex dispersion was filtered through a polypropylene filter having a pore size of 10.0 micrometers to remove dusts and so forth, and stored.

**[0190]**

<<Preparation of 25 weight % dispersion of reducing agent complex>>

In an amount of 10 kg of 1:1 complex of 2,2-methylenebis-(4-ethyl-6-tert-butylphenol) and triphenyl-phosphine oxide, and 10 kg of a 20 weight % aqueous solution of modified polyvinyl alcohol (Poval MP203, manufactured by Kuraray Co., Ltd.) were added with 16 kg of water, and mixed sufficiently to form slurry. The slurry was fed by a diaphragm pump to a sand mill of horizontal type (UVM-2, manufactured by Imex Co.) containing zirconia beads having a mean diameter of 0.5 mm, and dispersed for 3 hours and 30 minutes. Then, the slurry was added with 0.2 g of benzothiazolinone sodium salt and water so that the concentration of the reducing agent should become 25 weight % to obtain a solid microparticle dispersion of reducing agent complex. The reducing agent complex particles contained in the dispersion of reducing agent complex obtained as described above had a median diameter of 0.46 micrometers and the maximum particle size of 2.0 micrometers or less. The obtained reducing agent complex dispersion was filtered through a polypropylene filter having a pore size of 10.0 micrometers to remove dusts and so forth, and stored.

**[0191]**

<<Preparation of 10 weight % dispersion of mercapto compound>>

In an amount of 5 kg of 1-phenyl-2-heptyl-5-mercapto-1,3,4-triazole and 5 kg of a 20 weight % aqueous solution of modified polyvinyl alcohol (Poval MP203, manufactured by Kuraray Co., Ltd.) were added with 8.3 kg of water, and mixed sufficiently to form slurry. The slurry was fed by a diaphragm pump to a sand mill of horizontal type (UVM-2, manufactured by Imex Co.) containing zirconia beads having a mean diameter of 0.5 mm, and dispersed for 6 hours. Then, the slurry was added with water so that the concentration of the mercapto compound should become 10 weight % to obtain a mercapto compound dispersion. The mercapto compound particles contained in the mercapto compound dispersion obtained as described above had a median diameter of 0.40 micrometers and the maximum particle size of 2.0 micrometers or less. The obtained mercapto compound dispersion was filtered through a polypropylene filter having a pore size of 10.0 micrometers to remove dusts and so forth, and stored. The dispersion was filtered again through a polypropylene filter having a pore size of 10.0 micrometers immediately before use.

**[0192]**

<<Preparation of 20 weight % dispersion of Organic polyhalogenated compound 1>>

In an amount of 5 kg of tribromomethylnaphthylsulfone, 2.5 kg of a 20 weight % aqueous solution of modified polyvinyl alcohol (Poval MP203, manufactured by Kuraray Co., Ltd.) and 213 g of 20 weight % aqueous solution of sodium triisopropyl-naphthalene-sulfonate was added with 10 kg of water, and mixed sufficiently to form slurry. The slurry was fed by a diaphragm pump to a sand mill of horizontal type (UVM-2, manufactured by Imex Co.) containing zirconia beads having a mean diameter of 0.5 mm, and dispersed for 5 hours. Then, the slurry was added with 0.2 g of

benzothiazolinone sodium salt and water so that the concentration of the organic polyhalogenated compound should become 26 weight % to obtain an organic polyhalogenated compound dispersion. The organic polyhalogenated compound particles contained in the polyhalogenated compound dispersion obtained as described above had a median diameter of 0.36 micrometers and the maximum particle size of 2.0 micrometers or less. The obtained organic polyhalogenated compound dispersion was filtered through a polypropylene filter having a pore size of 3.0 micrometers to remove dusts and so forth, and stored.

**[0193]**

<<Preparation of 25 weight % dispersion of Organic polyhalogenated compound 2>>

As well as the above 20 weight % of organic polyhalogenated compound 1, but 5 kg of tribromomethyl (4-(2, 4, 6-triphenylsulfonyl) phenyl) sulfone is used in place of 5 kg of tribromomethylnaphthylsulfone. The is dispersed and is diluted to become 25 weight % to obtain an organic polyhalogenated compound dispersion. The organic polyhalogenated compound particles contained in the polyhalogenated compound dispersion obtained as described above had a median diameter of 0.38 micrometers and the maximum particle size of 2.0 micrometers or less. The obtained organic polyhalogenated compound dispersion was filtered through a polypropylene filter having a pore size of 3.0 micrometers to remove dusts and so forth, and stored.

**[0194]**

<<Preparation of 26 weight % dispersion of Organic polyhalogenated compound 3>>

The dispersion of Organic polyhalogenated compound 3 was prepared in the same manner as in the preparation of 20 weight % of organic polyhalogenated compound 1 above, except that 5 kg of tribromophenyl sulfonic acid is used in place of 5 kg of tribromomethylnaphthylsulfone, 5 kg of 20 weight % aqueous solution of modified MP203 was used, and the mixture was dispersed, diluted to obtain a mixture having a concentration of the organic polyhalogenated compound of 26 weight %, and filtered. The organic polyhalogenated compound particles contained in the polyhalogenated compound dispersion obtained as described above had a median diameter of 0.41 micrometers and the maximum particle size of 2.0 micrometers or less. The obtained organic polyhalogenated compound dispersion was filtered through a polypropylene filter having a pore size of 3.0 micrometers to remove dusts and so forth, and stored. Then, the dispersion was stored at 10°C or lower until use.

**[0195]**

<<Preparation of 25 weight % dispersion of Organic polyhalogenated compound 4>>

The dispersion of Organic polyhalogenated compound 4 was prepared in the same manner as in the preparation of 20 weight % of organic polyhalogenated compound 1 above, except that 5 kg of tribromomethyl-3-pentanoylaminophenylsulfone was used in place of 5 kg of tribromomethylnaphthylsulfone, and the mixture was dispersed, diluted to obtain a mixture having a concentration of the organic polyhalogenated compound of 25 weight %, and filtered. The organic polyhalogenated compound particles contained in the organic polyhalogenated compound dispersion obtained as described above had a median particle size of 0.41 micrometers and the maximum particle size of 2.0 micrometers or less. The obtained organic polyhalogenated compound dispersion was filtered through a polypropylene filter having a pore size of 3.0 micrometers to remove dusts and so forth, and stored.

**[0196]**

<<Preparation of 5 weight % solution of phthalazine compound>>

In an amount of 8 kg of modified polyvinyl alcohol (MP-203, manufactured by Kuraray Co.,

Ltd.) was dissolved in 174.57 kg of water and then added with 3.15 kg of 20 weight % aqueous solution of sodium triisopropylphthalenesulfonate and 14.28 kg of 70 weight % aqueous solution of 6-isopropylphthalazine to obtain a 5 weight % solution of 6-isopropylphthalazine.

**[0197]**

<<Preparation of 20 weight % dispersion of pigment>>

In an amount of 64 g of C.I. Pigment Blue 60 and 6.4 g of Demor N manufactured by Kao Corporation, and 250 g of water were mixed sufficiently to provide slurry. Then, 800 g of zirconia beads having a mean particle size of 0.5 mm were placed in a vessel together with the slurry and the slurry was dispersed by a dispersing machine (1/4G Sand Grinder Mill; manufactured by Imex Co.) for 25 hours to obtain a pigment dispersion. The pigment particles contained in the dispersion obtained as described above had a mean particle size of 0.21 micrometers.

**[0198]**

<<Preparation of 40 weight % SBR latex>>

SBR latex purified by ultrafiltration (UF) was obtained as follows. The SBR latex mentioned below diluted by 10 times with distilled water was diluted and purified by using an UF-purification module FS03-FC-FUYO3A1 (manufactured by Daisen Membrane System K.K.) until the ion conductivity became 1.5 mS/cm, and added with Sandet-BL (manufactured by sanyo chemical industries, Ltd.) to a concentration of 0.22 weight %. Further, the latex was added with NaOH and  $\text{NH}_4\text{OH}$  so that the ratio of  $\text{Na}^+$  ion: $\text{NH}_4^+$  ion should become 1:2.3 (molar ratio) to adjust pH to 8.4. At this point, the concentration of the latex was 40 weight %.

(SBR latex: a latex of -St(71)-Bu(26)-AA(3)-, wherein the numerals in the parentheses indicate the contents in terms of weight %, St represents styrene, Bu represents butadiene and AA represents acrylic acid)

The latex had the following characteristics: mean particle size of 0.1 micrometers, concentration of 45%, equilibrated moisture content of 0.6 weight % at 25°C and 60% RH, and ion conductivity of 4.2 mS/cm (measured for the latex stock solution (40%) at 25°C by using a conductometer, CM-30S, manufactured by Toa Electronics, Ltd.), pH 8.2.

<<Preparation of thermally processed image forming material-1,2>>

On the back surface side of the aforementioned support having undercoat layers, the coating solution for antihalation layer and the coating solution for back surface protective layer were simultaneously applied as stacked layers so that the applied solid content of the solid microparticle dye in the antihalation layer should be 0.04 g/m<sup>2</sup>, and the applied amount of gelatin in the back surface protective layer should be 1.7 g/m<sup>2</sup>, and dried to form a back layer. Then, on the side opposite to the back side, an image-forming layer Coated silver amount of the silver halide was 0.14 g/m<sup>2</sup>, intermediate layer, first protective layer and second protective layer were simultaneously coated in this order from the undercoat layer by the slide bead coating method as stacked layers to form a sample-1,-2 of thermally processed image recording material. The conditions of coating and drying were as follows. The coating was performed at a speed of 160 m/min. The gap between the tip of coating die and the support was set to be 0.10 to 0.30 mm, and the pressure in the reduced pressure chamber was adjusted to be lower than the atmospheric pressure by 196-882 Pa. Electrostatic charge of the support was eliminated by ionized wind before the coating. In the subsequent chilling zone, the coating solutions were cooled with air blow showing a dry-bulb temperature of 10-20°C. Then, the material was transported without contact, and dried with drying air showing a dry-bulb temperature of 23-45°C and a wet-bulb temperature of 15-21°C in a coil-shaped non-contact type drier. After the drying, the material was conditioned for its moisture content at 25°C and relative humidity of 40-60%, and heated so that the temperature of film surface should become 70-90°C. After the heating, the material was cooled to 25°C as a temperature of film surface. The prepared

thermally processed image recording material showed matting degree of 550 seconds for the photosensitive layer side, and 130 seconds for the back surface, in terms of Beck's smoothness. The film surface pH on the photosensitive layer side was measured to be 6.0.

**[0206]**

<<Preparation of thermally processed image forming material-3 and 4>>

Thermally processed image forming material-3 and 4 were prepared in the same manner as the preparation of thermally processed image forming material-1 and 2 except that the following coating solution for image-forming layer was used and yellow dye compound was removed from the coating solution for antihalation layer.

In an amount of 1.1 g of the 20 weight % aqueous dispersion of pigment obtained above, 103 g of organic acid silver salt dispersion B or C, 5 g of 20 weight % of aqueous solution of polyvinyl alcohol PVA-205 (Kuraray Co., Ltd.), 26 g of the 25 weight % dispersion of the reducing agent complex, 8.2 g in total of the dispersions of Organic polyhalogenated compound 3 and 4 (weight ratio = 1:3), 6.2 g of the 10 weight % dispersion of mercapto compound, 106 g of the 40 weight % aqueous solution of SBR latex (Tg: 24°C) undergone the ultrafiltration (UF) purification and pH adjustment and 18 ml of the 5 weight % solution of phthalazine compound were combined, and mixed sufficiently with 10 g of Silver halide mixed emulsion A immediately before coating to prepare a coating solution for image-forming layer. The coating solution was fed as it was to a coating die in such a feeding amount giving a coating amount of 70 ml/m<sup>2</sup> and coated to obtain thermally processed image forming material-3 and 4.

**[0207]**

<<Evaluation of photographic performance>>

Each thermally processed image recording material was light-exposed and heat-developed (at about 120°C) by using Fuji Medical Dry Laser Imager FM-DP L (equipped with a semiconductor laser of 660 nm and maximum output of 60 mW (IIIB)), and the obtained image was evaluated by a densitometer.

Further, each thermally processed image recording material was evaluated for an evaluation of photographic performance described, light transmittance state and forced time storage stability in Example 1 of JP-A-11-349325.

As a result, Dmin of each thermally processed image recording material was low, has a high sensitivity and an optical penetration of a complete level, was 5-6% of increasing rate of forced time, thus it was determined that light exposure image does not change by preserving.

**[0208]**

**[Advantageous effects of the invention]**

According to the present invention, it became possible to restrain an increase in viscosity by ultrafiltration concentrations, decrease at speed of ultrafiltration and blocking of pipelines by executing a dispersing operation before ultrafiltration conditions or during ultrafiltration concentrates and concentrated operation can be efficiently done. According to the present invention it also became possible to provide a thermally processed image recording material exhibiting low fog has high black concentration and low haze.

**【Abstract】**

**【Problems】** To provide a method for preparing an aqueous dispersion of grains of silver salt of an organic acid that enables efficient concentration with suppressing increase in viscosity in a concentration process by ultrafiltration, decrease in speed at ultrafiltration and blocking of pipeline.

**【Means for solving the problems】**

A method for preparing an aqueous dispersion of grains of silver salt of an organic acid that is obtained by dispersing the silver salt grains of the organic acid into an aqueous solvent; which comprises the steps of reacting (1) a solution containing silver ion in water or in a mixture of organic solvent and water with (2) a solution or suspension containing an alkali metal salt of the organic acid in water or in a mixture of an organic solvent and water, or in an organic solvent, to obtain a silver salt of the organic acid, and conducting dispersion with a high pressure homogenizer or high speed rotary homomixer in the presence of a dispersing agent, and removing by-product salts by ultrafiltration.
